### 9 Abstract:

10 High-quality hexagonal upconversion nanocrystals of  $\beta\text{-NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  were  
11 prepared through one-pot mild solvothermal synthesis. The crystal structure of  
12  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  can rapid transform from cubic ( $\alpha$ -) to  $\beta$ - phase in the presence of  
13 some salts, such as sodium hydrogen phosphate ( $\text{Na}_2\text{HPO}_4$ ). It was found that the size  
14 and structure of as-prepared  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  can be controlled by changing the  
15 molar ratio of phosphate to  $\text{Ln}^{3+}$  ( $\text{Ln}^{3+}$  represents the total amount of  $\text{Y}^{3+}$  and the  
16 doped rare earth elements such as  $\text{Yb}^{3+}, \text{Er}^{3+}$ ). The possible formation mechanism was  
17 proposed on the basis of XRD analysis and TEM observation of the products at the  
18 different reaction condition. The upconversion fluorescence at 550 nm of  
19  $\beta\text{-NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  nanocrystals with spherical structure and narrow size distribution  
20 was enhanced up to 22.5-fold compared to cubic nanocrystals ( $\alpha\text{-NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$ ).  
21 This study also is expected to be provided a reference for exploration of other  
22 complex with controllable structure and optical properties.

## 1 **1 Introduction**

2       The nano- and micro-structure materials have attracted considerable  
3 attention due to their potential applications in various fields during the  
4 past decades.<sup>1-5</sup> The chemical and physical properties of the materials are  
5 related to their morphologies, sizes and crystal structure.<sup>6, 7</sup> Therefore,  
6 many works have been done surrounding the research about the physical  
7 mechanism and the method for controlling the crystallization processes  
8 for obtains the desired shape of crystals.<sup>7, 8</sup> Some theoretical models also  
9 have been introduced to explain the relationship between equilibrium  
10 morphology and crystal structure.<sup>6, 8</sup> However, it is still a challenge to  
11 develop a facile approach to manipulate and control the morphologies and  
12 crystal phase of various inorganic crystals owing to the complexity of  
13 crystal structures and compositions of these materials.<sup>9</sup> Therefore, the  
14 synthetic method with no expensive reagents and complex equipments for  
15 controlling the morphologies and structure of crystals is attracting great  
16 interest. Some additives, such as polyvinyl pyrrolidone (PVP)<sup>6</sup>, ethylene  
17 diamine tetraacetic acid (EDTA)<sup>10</sup>, ethanediamine<sup>11</sup>, sodium citrate and  
18 AOT<sup>12</sup>, can be used to control the phase, morphology, and size of crystal  
19 materials. Ongoing efforts have been performed to examine the surface  
20 energies of crystals in the presence and absence of additives in order to  
21 confirm the role of these additives to structured materials.<sup>13, 14</sup> Some salts

1 were also used as the additive to control the morphology and structure of  
2 some crystals.<sup>15-18</sup> However, the action of surfactants for controlling the  
3 phase, morphology of crystals is still not perfect.<sup>6</sup>

4 Among these crystal materials, upconversion nanocrystals (UCNCs)  
5 with the advantages of no background fluorescence, perfect tissue  
6 penetration and low toxicity have been applied in the fields of bioanalysis,  
7 disease diagnosis, optical communication and solar cells.<sup>19-21</sup> As one of  
8 host matrixes, sodium yttrium fluoride (NaYF<sub>4</sub>) with low phonon energies  
9 ( $<400\text{ cm}^{-1}$ )<sup>12</sup> and a high refractive index (1.430-1.470 m<sup>2</sup>/W) has been  
10 considered as an excellent host matrix for down-conversion (DC) and  
11 up-conversion (UC) nanocrystals synthesis<sup>12</sup>. The ytterbium and erbium  
12 co-doped sodium yttrium fluoride (NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup>) nanocrystals is one  
13 of the most efficient upconversion fluorophores among various kinds of  
14 upconversion materials<sup>5</sup> and cubic ( $\alpha$ -) and hexagonal ( $\beta$ -) phases are the  
15 two polymorphic forms for it. It is known that the  $\beta$ - NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup>  
16 crystals exhibits considerable higher fluorescence efficiency than that of  
17  $\alpha$ -NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup> crystals.<sup>7, 12</sup> Thermal decomposition method was used  
18 for the synthesis of NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup> nanocrystals frequently.<sup>22-24</sup>  
19 High-quality UCNCs can be successfully produced from the metal  
20 trifluoroacetate precursors ((CF<sub>3</sub>COO)<sub>3</sub>Ln) in the presence of high boiling  
21 point organic solvents.<sup>23</sup> However, the generation of toxic by-products,  
22 expensive and air-sensitive metal precursors and rigorous synthesis

1 conditions limited its operability<sup>25</sup>. The hydro/solvothermal method with  
2 the simple operations (one-pot synthesis) was also used for preparing  
3 inorganic submicrocrystalline materials.<sup>10, 26</sup> However, long hydrothermal  
4 time (>10 h) and a higher temperature (>200 °C) are needed to synthesize  
5 the phosphors with  $\beta$ - phase ( $\beta$ -NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup>).<sup>7</sup> Many methods have  
6 been used to control morphology and phase of crystal. Wu reported the  
7 hydrothermal growth of  $\beta$ -NaYF<sub>4</sub> by altering the hydrothermal reaction  
8 temperature and the reaction time.<sup>27</sup> Solvothermal conditions were  
9 employed to fabricate different microstructures of  $\beta$ -NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup><sup>28</sup>  
10 and NaYF<sub>4</sub>.<sup>29</sup> By adjusting solvent composition and F<sup>-</sup>/Ln<sup>3+</sup> molar ratio  
11 can fabricate  $\beta$ -NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup> nanocrystals at 240 °C by using a facile  
12 hydrothermal method.<sup>7</sup> However, spherical nanocrystals with small size  
13 and high-efficiency fluorescent are preferred for biological applications, it  
14 is still a challenge to fabricate well-defined NaYF<sub>4</sub> crystals with the ideal  
15 size, morphology and crystal phase.<sup>9</sup> To the best of our knowledge, there  
16 is no report on using inorganic salts to control the morphologies and  
17 crystal structure of UCNCs in reaction process.

18 In this paper, we report a facile hydrothermal approach for the  
19 fabrication  $\beta$ -NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup> nanocrystals with well-defined  
20 morphology by assist of Na<sub>2</sub>HPO<sub>4</sub> which can regulate the nucleation and  
21 growth behaviour of the crystals with considerably mild conditions and  
22 shortened time. More specifically, the other inorganic salts, such as NaCl,

1 Na<sub>2</sub>SO<sub>4</sub>, (NH<sub>4</sub>)<sub>2</sub>HPO<sub>4</sub>, with different degrees, can also promote the rapid  
2 transformation of the crystal from  $\alpha$ - phase ( $\alpha$ -NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup>) to  
3 high-quality  $\beta$ -NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup> crystals. The morphologies and sizes can  
4 be controlled by simply tuning the molar ratio of phosphate to Ln<sup>3+</sup> and  
5 the possible formation mechanism for the phase evolution process of  
6 NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup> is also presented. Furthermore, the upconversion  
7 fluorescence properties of NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup> were also investigated. This  
8 method for UCNCs with controllable phase is expected to expand in  
9 exploration of other inorganic crystals complex.

## 1 **2 Experimental**

### 2 **2.1 Apparatus**

3 The crystal phase of the products was identified by a Rigaku 2500  
4 (Japan) X-Ray Diffractometer (XRD) with  $2\theta$  range from  $10^\circ$  to  $70^\circ$  at a  
5 scanning rate of  $4^\circ$  per minute, with Cu K $\alpha$  irradiation ( $k=1.5406 \text{ \AA}$ ). The  
6 size and morphology of the transmission electron microscopy (TEM)  
7 images were characterized using a JEOL-1230 TEM (JEOL, Japan). The  
8 fluorescence spectra were measured using an F-4500 fluorescence  
9 spectrophotometer (Hitachi Ltd, Japan) with an external 980 nm laser  
10 diode (Hi-Tech Optoelectronic Co., Ltd. China) as the excitation source.  
11 All samples were prepared using ultrapure water obtained from a Mill-Q  
12 water purification system (Millipore,  $\geq 18 \text{ M}\Omega \text{ cm}$ ).

### 13 **2.2 Materials**

14 Rare-earth oxides used in this work, including yttrium oxide ( $\text{Y}_2\text{O}_3$ ),  
15 ytterbium oxide ( $\text{Yb}_2\text{O}_3$ ) and erbium oxide ( $\text{Er}_2\text{O}_3$ ), were purchased from  
16 Sinopharm Chemical Reagent Co., Ltd. (Shanghai, China) and dissolved  
17 in hot nitric acid and then dissolved in deionized water to achieve final  
18 concentrations of 0.4 M, 0.05 M, and 0.05 M, respectively. Sodium  
19 phosphate dibasic dodecahydrate ( $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$ ), hydrofluoric acid  
20 (HF), sodium hydroxide (NaOH), nitric acid ( $\text{HNO}_3$ ), cetyltrimethyl

1 ammonium bromide (CTAB) and EDTA were of analytical grade from  
2 Sinopharm Chemical Reagent Co., Ltd. (Shanghai, China) and were used  
3 as received without further purification.

### 4 **2.3 The synthesis of NaYF<sub>4</sub>: Yb<sup>3+</sup>,Er<sup>3+</sup>**

5 The UCNCs were prepared according to a modified synthesis  
6 procedure<sup>10</sup>, 1.315 mL of 0.4 M Y(NO<sub>3</sub>)<sub>3</sub>, 0.42 mL of 0.05 M Yb(NO<sub>3</sub>)<sub>3</sub>  
7 and 0.105 mL of 0.05 M Er(NO<sub>3</sub>)<sub>3</sub> were added to a aqueous solution (2  
8 mL) containing different amounts of Na<sub>2</sub>HPO<sub>4</sub>·12H<sub>2</sub>O. Under  
9 ultrasonication, 0.2925 g EDTA was added to the solution and the pH of  
10 the mixture was adjusted to 8.5 with HNO<sub>3</sub> or NaOH. Then, 10 mL glycol  
11 and 0.0675 g CTAB were added to the solution. After the solution became  
12 clear, another aqueous solution containing 0.5 mL HF was dropwise  
13 added to the mixture and adjusted the pH to 2. After vigorous stirring at  
14 room temperature for 30 min, the colloidal solution were transferred into  
15 a 50 mL Teflon-lined autoclave, sealed and maintained at 180 °C for 1 -  
16 12 h. The systems were then allowed to naturally cool to room  
17 temperature. The final products were collected by means of centrifugation,  
18 washed with ethanol and deionized water for several times to remove any  
19 possible remnants, and then dried in vacuum at 70 °C to obtain the dried  
20 UCNCs powder.

## 1 **3 Results and Discussion**

### 2 **3.1 The rapid transformation of NaYF<sub>4</sub>: Yb<sup>3+</sup>,Er<sup>3+</sup> nanocrystals from** 3 **cubic to hexagonal**

4 It has been reported that NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup> nanocrystals can be  
5 obtained using hydro/solvothermal method with EDTA and CTAB as  
6 additives for controlling the size and prevent the nanocrystals from  
7 aggregating and the formation of pure β-NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup> nanocrystals  
8 should hydrothermal reaction 96 h.<sup>10</sup> However, It was found that the rapid  
9 crystal phase transformation of the NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup> nanocrystals from α-  
10 to β- phase can carry out in the presence of Na<sub>2</sub>HPO<sub>4</sub>·12H<sub>2</sub>O. And the  
11 growth rate of NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup> nanocrystals can be controlled strictly by  
12 varying the molar ratio of phosphates to Ln<sup>3+</sup> (Ln<sup>3+</sup> represents the total  
13 amount of Y<sup>3+</sup>, Yb<sup>3+</sup> and Er<sup>3+</sup>) in the aqueous model system. The XRD  
14 patterns in Fig. 1 of NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup> nanocrystals obtained at different  
15 molar ratios (0, 1, 2, 3 and 4) of Na<sub>2</sub>HPO<sub>4</sub>·12H<sub>2</sub>O to Ln<sup>3+</sup> show crystal  
16 structure evolution. When other parameters are kept unchanged and  
17 increase the concentration of Na<sub>2</sub>HPO<sub>4</sub>·12H<sub>2</sub>O, it can quickly promote the  
18 phase transformation from α- to β- phase. For example, in the absence of  
19 Na<sub>2</sub>HPO<sub>4</sub>·12H<sub>2</sub>O, only highly crystalline α- planes, such as (111), (200),  
20 (221) and (311) (JCPDS No. 77-2042) (α-NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup>) was  
21 presented at 180 °C for 3.5 h (Fig. 1 curve a). However, mixed-phase (α-

1 and  $\beta$ -) products are obtained when  $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$  is added. The  
2 relative peak strength of diffraction peaks of the (100), (110), (101), (111),  
3 (201) and (211) planes of standard  $\beta$ - $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  structure gradually  
4 increase with the molar ratios of phosphates to  $\text{Ln}^{3+}$  from 1 to 3 (Fig. 1  
5 curve b - d). The purity peaks of  $\beta$ - phase  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  can be formed  
6 when the molar ratios increases to 4 (Fig. 1 curve e). The rapid  
7 transformation of crystal phase of  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  from  $\alpha$ - to mixed  
8 phase and ultimately to  $\beta$ - phase with increase of  $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$   
9 indicated that phosphate affect the crystal transformation in the  
10 hydrothermal process significantly.

11 The TEM characterization was performed to confirm the changes in  
12 morphology. As shown in Fig. 2, the  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  nanocrystals with  
13 an average diameter of 24.5 nm (Fig. 2 A) which were prepared without  
14 phosphate were mainly composed of spherical nanocrystals. The HRTEM  
15 of this nanocrystals shows lattice distance of 0.28 nm which correspond  
16 to the d spacing of the (200) lattice planes of the  $\alpha$ - $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$   
17 structure (Fig. 2 B). A standard  $\alpha$ - structure can be found from the  
18 diffraction rings in the selected area electron diffraction (SAED) pattern  
19 (Fig. 2 C) which can be assigned to the (111), (200), (221) and (311)  
20 planes, respectively. This findings demonstrate once again that the  
21 crystals obtained without phosphate have  $\alpha$ - phase structures  
22 corresponding to the XRD patterns in Fig. 1 curve a. Although the

1 as-prepared  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  with the mixed crystal phase prepared in the  
2 present of  $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$  still keep the mainly spherical morphology,  
3 the average diameter of these crystals increase to 30 nm when the molar  
4 ratios increase to 2 (as shown in Fig. 2 D). In addition, the lattice fringes  
5 show spaces of 0.314 nm (Fig. 2 E) which is matched well with the (111)  
6 lattice planes of the  $\alpha\text{-NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  structure. Owing to the most  
7 particles remaining in  $\alpha$ - phase, the diffraction rings in the SAED pattern  
8 (Fig. 2 F) remain the planes of standard  $\alpha$ - phase planes and not easy to  
9 find  $\beta$ - phase planes. The morphology of  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  nanocrystals  
10 obtained at 180 °C for 3.5 h with the molar ratio of  $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$  to  
11  $\text{Ln}^{3+}$  is 4 has tended to become tetragonum as well as the average  
12 diameter of the crystals become to 70 nm (Fig. 2 G). The interplanar  
13 spacings of 0.30 nm and 0.286 nm correspond to d spacing values of the  
14 (100) and (101) planes of  $\beta\text{-NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  structure (Fig. 2 H). The  
15 diffraction rings of the SAED pattern shown in Fig. 2 I can be associated  
16 with the (100), (110), (101) and (201) planes of the standard  
17  $\beta\text{-NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  structure. The results from TEM of  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$   
18 nanocrystals obtained in the presence of phosphates was compared with  
19 that of XRD patterns in Fig. 1, showing good agreement with each other.  
20 These gives further evidence of the fast formation of  $\beta\text{-NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$   
21 nanocrystals with the assist of  $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$  in the reaction system.  
22 Based on the above analysis, we can conclude that the  $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$

1 has significant influence on the structures and shapes of the final products  
2 ( $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$ ) in this reaction system.

3 Temperature is another significant factor for controlling the  
4 crystallization of nanocrystals among the experimental variables.<sup>30</sup> The  
5 effect of hydrothermal reaction temperature on the phase of the  
6  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  nanocrystals was investigated and XRD patterns of the  
7 prepared particles was shown in Fig. S 1. The particles processed at  
8 different temperatures displayed distinctively different XRD patterns. The  
9  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  nanocrystal also exhibit mixed phase at 160 °C for 3 h  
10 when  $\text{Na}_2\text{HPO}_4/\text{Ln}^{3+}$  is 4. Moreover, with the increase of hydrothermal  
11 reaction temperature to reach 180 °C, the crystalline phase of the particles  
12 trend to  $\beta$ - phase with the intensities of the diffraction peaks of  $\alpha$ - phase  
13 significantly decreased. When the temperature increased, pure  $\beta$ - phase  
14 can be obtained at 200 °C for 3 h with the same amount of  $\text{Na}_2\text{HPO}_4$ .  
15 When we further increased the  $\text{Na}_2\text{HPO}_4/\text{Ln}^{3+}$  molar ratio and reaction  
16 temperature, less time was needed to obtain  $\beta$ - $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$   
17 nanocrystals. For example, the  $\beta$ - $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  nanocrystals can be  
18 achieved at 200 °C for 2 h (Fig. S2). The synthesis conditions of pure  $\beta$ -  
19 phase are summarized in Table S1. However, with increasing in  
20 phosphate concentration in this reaction system, the  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$   
21 with rod-like hexagonal phase was prepared (Fig. S 3), which agrees with  
22 the reported results.<sup>7</sup> In order to obtain the  $\beta$ - $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$

1 nanocrystals with the perfect size and morphology, we chose  $\text{Na}_2\text{HPO}_4$  to  
2  $\text{Ln}^{3+}$  of 4 for further studying.

### 3 **3.2 Possible growth mechanism of $\beta\text{-NaYF}_4\text{:Yb}^{3+},\text{Er}^{3+}$ nanocrystals in** 4 **the presence of phosphate.**

5 We further investigated the influence of reaction time to  
6  $\text{NaYF}_4\text{:Yb}^{3+},\text{Er}^{3+}$  nanocrystals in the assistance of  $\text{Na}_2\text{HPO}_4$ . It is well  
7 known that the growth profile of  $\text{NaYF}_4\text{:Yb}^{3+},\text{Er}^{3+}$  crystals is from  
8 amorphous form to  $\alpha$ - phase and finally turn into the  $\beta$ - phase.<sup>7, 30</sup> To  
9 further verify the process of crystal growth, a series of XRD patterns of  
10  $\text{NaYF}_4\text{:Yb}^{3+},\text{Er}^{3+}$  crystals by assistant of  $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$  (the  
11  $\text{Na}_2\text{HPO}_4$ -to- $\text{Ln}^{3+}$  molar ratio was 4 : 1) at 180 °C for different  
12 hydrothermal reaction time were collected and presented in Fig. 3 A.  
13 Only the diffraction peak of  $\alpha\text{-NaYF}_4\text{:Yb}^{3+},\text{Er}^{3+}$  nanocrystals can be  
14 observed when the reaction time was 1 h (Fig. 3 A curve 1 h) and a new  
15 diffraction peak of  $\beta$ - phase of  $\text{NaYF}_4\text{:Yb}^{3+},\text{Er}^{3+}$  emerges for 2 h (Fig. 3 A  
16 curve 2 h). The fraction of the  $\beta$ - phase increased substantially when the  
17 time reached to 3 h, but  $\alpha$ - phase was still present (Fig. 3 A curve 3 h).  
18 However, the  $\alpha$ - phase disappeared completely, and pure  $\beta$ - phase can be  
19 successfully obtained at 180 °C for only 3.5 h (Fig. 3 A curve 3.5 h). The  
20 X-ray diffraction patterns of these crystals in Fig. 3 A match well with  
21 those calculated for  $\alpha$ - phase (JCPDS No. 77-2042) and  $\beta$ - phase (JCPDS

1 No. 16-0334)  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$ . Apparently, the crystal formation in the  
2 presence of phosphate follow the process of  $\alpha$ - phase to the mixed phase  
3 and ultimately to  $\beta$ - phase. As a comparison, the formation process of  
4  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  crystals without the  $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$  in the reaction  
5 system was also investigated and the results are present in Fig. 3 B. Only  
6 diffraction peak of  $\alpha$ - phase of  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  crystals can be observed  
7 at 180 °C for 3 h. The diffraction peak of  $\beta$ - phase of  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$   
8 crystals can only be found until the hydrothermal reaction time increased  
9 to 6 h (Fig. 3 B curve 6 h), and without obvious changes even though the  
10 reaction time increase to 12 h (Fig. 3 B curve 12 h). With reference to the  
11 test results, it has the similar crystals conformation process for  
12  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  crystals whether  $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$  exists in the reaction  
13 system or not. That is to say,  $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$  has greatly accelerated the  
14 phase transitions process from  $\alpha$ - to  $\beta$ - phase. Therefore, these facts also  
15 proved that the phosphate plays the more significant role in accelerating  
16 structure transition of  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  from  $\alpha$ - to  $\beta$ - phase rather than  
17 changing the growth pattern of  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  crystals.

18 The morphologies of the  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  crystals by assistant of  
19  $\text{Na}_2\text{HPO}_4$  at 180 °C for different reaction time are investigated (Fig 4).  
20 Fig. 4 A shows some representative TEM images of the  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$   
21 nanocrystals prepared by assistant of  $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$  ( $\text{PO}_4^{3-}/\text{Ln}^{3+} = 4$ )  
22 when the reaction time was 1 h. All of these nanocrystals in Fig. 4 A are

1 highly uniform with spherical shapes and an average diameter of 22.4 nm  
2 which are similar to the nanocrystals obtained in the absence of phosphate.  
3 However, the particle sizes increased rapidly than the particles in Fig. 4 A  
4 with the increase of reaction time. It is clear that small crystals exists  
5 around the surface of the  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  crystals with larger sizes (Fig 4  
6 B and C) by increasing the solvothermal time from 2 h to 3 h and the  
7 crystals become irregular. By increasing the time to 3.5 h, the small  
8 nanocrystals can be completely transformed into uniform nanocrystals  
9 with little changes on their size and morphology. The fairly uniform  
10 well-defined  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  nanocrystals with an average length of 70  
11 nm was obtained after hydrothermal reaction 3.5 h (Fig 4 D). The  
12 corresponding particle size distribution histograms of  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$   
13 nanocrystals from different reaction time are shown in Fig. S 4. The  
14 results mentioned above demonstrated that the growth pattern of crystals  
15 in the presence of phosphate is similar to the formation processes of  
16  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  nanocrystals in other reaction system and the size of it  
17 increases with time.<sup>7</sup> There are a few reports demonstrated that the  
18 morphology and crystal phase of  $\text{NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$  can be controlled via  
19 changing the fluoride sources and the  $\text{F}/\text{Ln}^{3+}$  molar ratio during the  
20 hydrothermal process<sup>7, 8, 28, 31</sup>. The small nuclei can be generated when the  
21  $\text{F}^-$  ions in the solution to react with  $\text{Ln}^{3+}$  through strong coordination  
22 interaction. These nuclei can only grow into  $\alpha\text{-NaYF}_4:\text{Yb}^{3+},\text{Er}^{3+}$

1 nanocrystals in a very short reaction time, which is a high temperature  
2 metastable phase. When the reaction time is increased, the unstable  
3  $\alpha$ -NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup> nanocrystals trend to transform to  $\beta$ -NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup>  
4 nanocrystals (a thermodynamically stable phase) through a  
5 dissolution–renucleation process known as ostwald ripening.<sup>32,33</sup> It is also  
6 reported that density of Ln<sup>3+</sup> on the surfaces of hexagonal crystals larger  
7 than that of  $\alpha$ - crystals.<sup>34</sup> Therefore, the excessive F<sup>-</sup> more trend to  
8 combine with the Ln<sup>3+</sup> of surface of hexagonal crystals, such as (100),  
9 (110), (101), (201) and (220), to decrease the average number of dangling  
10 bonds and chemical potential of this crystal plane and results in faster  
11 growth along this direction with anisotropic growth thus to promote the  
12 rapid transformation of crystalline from  $\alpha$ - to  $\beta$ - phase.<sup>7</sup> The transform  
13 mechanism of NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup> in this work maybe it is the anions liking  
14 the F<sup>-</sup> which play an important role in accelerating the rapid growth and  
15 transformation of the nuclei of NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup>. A possible phase and  
16 morphology evolution mechanism in this paper is shown in Fig. 5. The  
17 abundant phosphate anions interact with the cations (Ln<sup>3+</sup>) on the surface  
18 of  $\beta$ - crystal during the reaction and results in faster growth along this  
19 direction. It is means that negative ions can be absorbed to the growing  
20 nanocrystals' surfaces via physical and chemical bonding to prompt the  
21 formation of a uniform  $\beta$ - phase of NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup>. To confirm this  
22 assume, different sodium salts with the same concentration of Na<sup>+</sup> (the

1 Na<sup>+</sup>-to-Ln<sup>3+</sup> molar ratio was 8) were investigated to explore the influence  
2 on the crystal structure of NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup> nanocrystals at 180 °C for 3 h.  
3 Compared to the blank sample without any sodium salts system (Fig. 6  
4 curve a), the XRD pattern of NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup> in NaCl system (Fig. 6  
5 curve b) and Na<sub>2</sub>SO<sub>4</sub> system (Fig. 6 curve c) clearly show that these  
6 sodium salts can also contribute to the transformation of crystals from α-  
7 to β- phase but with different effects. The intensities of the diffraction  
8 peaks of β- shapes also increase significantly when (NH<sub>4</sub>)<sub>2</sub>HPO<sub>4</sub> (Fig. 6  
9 curve e) was used to replace Na<sub>2</sub>HPO<sub>4</sub> (Fig. 6 curve d) in the same  
10 condition. The slight differences of (NH<sub>4</sub>)<sub>2</sub>HPO<sub>4</sub> and Na<sub>2</sub>HPO<sub>4</sub> with the  
11 same concentration of PO<sub>4</sub><sup>3-</sup> to the transition from α- to β- phase may  
12 attribute to the NH<sub>4</sub><sup>+</sup> which may affect the pressure of the reaction system.  
13 These results demonstrated that the influence on the transformation of  
14 NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup> nanocrystal originated in anion rather than sodium ions.  
15 Thus, compared to Cl<sup>-</sup> and SO<sub>4</sub><sup>2-</sup>, the phosphate anions with the most  
16 obvious effect to promote the rapid transformation of NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup>  
17 nanocrystals from α- to β- phase may owe to the strongest complexation  
18 of phosphate anions to Ln<sup>3+</sup>.<sup>35</sup>

### 19 3.3 Upconversion fluorescence properties

20 The upconversion fluorescence of NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup> nanocrystals  
21 synthesized with different PO<sub>4</sub><sup>3-</sup>/Ln<sup>3+</sup> ratios (0 - 4) has been studied and

1 its upconversion fluorescence spectrum with different phase  
2 compositions and sizes are shown in Fig. 7 A. The fluorescence  
3 spectrum of UCNCs reveals typical emission bands at 535 nm, 550 nm  
4 and 660 nm under NIR excitation (980 nm), which can be assigned to  
5 the  $^4H_{11/2} \rightarrow ^4I_{15/2}$ ,  $^4S_{3/2} \rightarrow ^4I_{15/2}$  and  $^4F_{9/2} \rightarrow ^4I_{15/2}$  transitions of the  $Er^{3+}$   
6 ions, respectively (Fig S. 5). Keeping all the other experimental  
7 measurements conditions (e.g., excitation source, excitation intensity  
8 and concentration) unchanged, the green upconversion fluorescence  
9 intensity at 550 nm (Fig. 7 A) and 660 nm (inset of Fig.7 A) of  
10  $NaYF_4:Yb^{3+},Er^{3+}$  nanocrystals increase with the ratios of  $PO_4^{3-}$  to  $Ln^{3+}$   
11 from 0 to 4. Fig. 7 B is the fluorescence intensity ratios of integral  
12 intensity of green (550 nm) and red (660 nm) emission of the crystals  
13 with different phase. It is clear that the fluorescence intensity of pure  
14  $\beta$ - $NaYF_4:Yb^{3+},Er^{3+}$  nanocrystals is about 22.5 times at 550 nm and 12.9  
15 times at 660 nm higher than those of pure  $\alpha$ - $NaYF_4:Yb^{3+},Er^{3+}$ ,  
16 respectively (Fig.7 B). The fluorescence brightness of  $NaYF_4:Yb^{3+},Er^{3+}$   
17 nanocrystals with different phase compositions, i.e., pure  $\alpha$ - phase,  $\alpha/\beta$   
18 mixed phase, and pure  $\beta$ - phase, distinct from each other excited with a  
19 980 nm CW laser (inset of Fig. 7 B). As known to all that the phase,  
20 morphologies and particle size of  $NaYF_4:Yb^{3+},Er^{3+}$  nanocrystal  
21 attributed to the upconversion fluorescence intensities.<sup>9</sup>  
22  $\beta$ - $NaYF_4:Yb^{3+},Er^{3+}$  nanocrystal has much higher fluorescence efficiency

1 than that of  $\alpha$ -NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup>,<sup>7,8</sup> and the crystals with larger size result  
2 in lower surface defects and stronger emission.<sup>9</sup> The NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup>  
3 nanocrystals prepared in this paper have larger sizes and hexagonal  
4 phase. Based on this fact, the enhanced fluorescence may be caused by  
5 the different particle size and phase. It was also suggested that the  
6 upconversion fluorescence efficiency of NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup> nanocrystals  
7 depend on its structure and crystal growth characterization.

#### 8 **4 Conclusion**

9 In summary, the  $\beta$ -NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup> nanocrystals have been  
10 successfully achieved using a simple and manageable hydrothermal  
11 method by assist of phosphate and templates and catalysts free. Through  
12 the simple manipulation of the phosphate to Ln<sup>3+</sup> ratio, the nanocrystals  
13 with different structure and sizes can be prepared. The high purity  $\beta$ -  
14 phase crystal can be obtained at relatively low temperatures (180 °C) and  
15 in a very short period of time (< 3.5 h). And then, The  $\beta$ -NaYF<sub>4</sub>:Yb<sup>3+</sup>,Er<sup>3+</sup>  
16 nanocrystals synthesized here with small sizes (70 nm) and spherical  
17 morphology are expected to meet the requirements of biological  
18 applications. This synthetic strategy by adjusting the amount of inorganic  
19 salts and other reaction parameters can also be extended to the  
20 controllable synthesis of other inorganic compounds.

## Graphical Abstract

- High-quality hexagonal nanocrystals ( $\beta\text{-NaYF}_4\text{:Yb}^{3+},\text{Er}^{3+}$ ) was obtained in aqueous solution via a facile hydrothermal route at relatively low temperature and in a short time.
- The size and structure of as-prepared  $\text{NaYF}_4\text{:Yb}^{3+},\text{Er}^{3+}$  can be controlled by changing the molar ratio of some salts to  $\text{Ln}^{3+}$  ( $\text{Ln}^{3+}$  represents the total amount of  $\text{Y}^{3+}$  and the doped rare earth elements such as  $\text{Yb}^{3+}$ ,  $\text{Er}^{3+}$ ), such as  $\text{Na}_2\text{HPO}_4$ .
- The  $\beta\text{-NaYF}_4\text{:Yb}^{3+},\text{Er}^{3+}$  nanocrystals with the relatively small size, spherical morphology and strong fluorescence are expected.
- This synthetic strategy by adjusting the amount of inorganic salts can also be extended to the controllable synthesis of other inorganic compounds.
