## 12 Abstract:

A new metal-organic framework, namely,  $\{[Cu(bib)_2] \cdot NO_3 \cdot 4H_2O\}_n$  (1) (bib = 13 2,3-bis(4-pyridyl)butane), was synthesized and characterized. In the structure of 1, 14 15 nitrogen atoms of four bib ligands bind to the tetrahedrally coordinated metal ion. The bib ligands act as linear bidenate linkers to form a four-fold interpenetrated 3D framework 16 with a **dia**-like topology. The  $H_2$  uptake of the dehydrated coordination framework 1 was 17 estimated using a computational method based on Connolly's algorithm, indicating that 18 19 adsorbed H<sub>2</sub> is predominantly located around the outer surface of the pore through multipoint interactions with the inner surface of dehydrated 1'. The material has no 20 significant adsorption for CO<sub>2</sub> and N<sub>2</sub> gas upon desolvation by long-time thermal 21 activation, indicating that access to the void space is blocked by the large and immovable 22 23 anions. The luminescent properties of sample 1 and dehydrated sample 1' were also 24 explored.

25 Keywords: Gas sorption; interpenetration; luminescence

26

# 27 Introduction

Materials called metal-organic frameworks (MOFs), a term introduced in the early 1990's by Robson, Yaghi, Zaworotko and James, describes a class of porous polymeric materials that consist of metal ions linked together by organic bridging ligands [1]. The porous yet rigid nature of these coordination networks has since then attracted substantial attention, mainly because of their potential to sustain permanent porosity with specific surface areas surpassing even those of the well-known zeolites and porous silicates. Their

1 extraordinarily low densities and high surface areas make these materials extremely 2 useful in a wide range of applications that range from adsorption, storage and separation 3 of gases such as hydrogen or methane, over capture of carbon dioxide, to heterogeneous catalysis, to name just a few [1]. Thanks to the large variety of metal centers, commonly 4 called nodes, and of organic bridging ligands, referred to as linkers, there is a virtually 5 limitless possibility of combination of secondary building units that can be assembled 6 7 interesting MOFs. This extreme diversity does also pose challenges, both for categorizing the different classes of MOFs, and for predicting which molecular architecture - or 8 9 topology might form with a selection of nodes and linkers under reaction conditions [2-6]. Both of these problems have led to the establishment of a complete new subject in solid 10 state sciences now commonly called "Reticular Chemistry", which tries to describe and 11 explain the design of solid materials from molecular building blocks. 12

One gateway towards the formation of highly porous MOF like materials is the use of 13 long extended linkers. A side effect of this strategy is the possibility to also form 14 interpenetrating networks, *i.e.* structures with entangled frameworks not connected 15 16 through any covalent interactions. This subcategory of MOFs encompasses a variety of interesting topological species such as *e.g.* polyknot and polycatenation compounds. The 17 formation of entangled coordination polymers is additionally promoted by the use of not 18 only elongated but also flexible organic linkers. For example, the flexible organic linker 19 20 1,2-bis(4-pyridyl)ethane is an excellent building block to construct different MOFs with well properties[7-11]. Thus, one effective way to modulate the type of entangled 21 22 topological motif is to vary the flexibility and length of the ligand. We have been interested in the syntheses and characterization of entangled MOFs containing the 23 24 extended organic linker 2,3-bis(4-pyridyl)butane, which so far has led to the formation of  $2D \rightarrow 2D$  parallel interpenetrated frameworks with polyrotaxane and polycatenane 25 character [12]. 26

The two main factors which affect the adsorption of gases in a microporous solid are: (a) the affinity of the surface for the adsorbates, and (b) the confinement effects generated within the cavities from the overlap of the potential energy surfaces of the guest molecules with the atoms of the host framework. The former factor can be directed through the functionalization of the MOFs, which has been investigated vigorously [13].

The functionalization method utilizes e.g. linkers containing halogen atoms, amine, 1 2 amide, or alkyl groups. Postsynthetic modifications have also been described. However, 3 the above method is confined by chemical incompatibilities of functional groups with the MOF assembly, and also by the rigidity of the MOF itself. Recently, a few of MOFs were 4 5 prepared with using of flexible linkers [14-15]. Extending our previous work on the self-assembly of novel topological coordination polymers based on the conformationally 6 7 flexible bib ligand, herein, we report the compound  $\{[Cu(bib)_2] \cdot NO_3 \cdot 4H_2O\}_n$  (1) (bib = 2,3-bis(4-pyridyl)butane), which shows 4-fold interpenetrated 3D framework with a 8 9 dia-like topology. Furthermore, its gas adsorption and luminescence properties are discussed in detail. 10

11 Experimental

# 12 Materials and Method

13 All reagents were purchased from commercial sources and used as received. IR spectra were recorded with a Perkin-Elmer Spectrum One spectrometer in the region 14 4000–400cm<sup>-1</sup> using KBr pellets. TGA were carried out with a Metter–Toledo TA 50 in 15 dry dinitrogen (60mL.min<sup>-1</sup>) at a heating rate of 5°C min<sup>-1</sup>. X-ray powder diffraction 16 (XRPD) data were recorded on a Rigaku RU200 diffractometer at 60KV, 300mA with Cu 17  $K_a$  radiation ( $\lambda = 1.5406$  Å), with a scan speed of 2 °C/min and a step size of 0.013° in 20. 18 Luminescence spectra for crystal solid samples were recorded at room temperature on an 19 20 Edinburgh FLS920 phosphorimeter (USA). All the gas sorption isotherms were measured by using a ASAP 2020M adsorption equipment. 21

22 X-ray Crystallography

23 Single crystal X-ray diffraction analysis of the compound was carried out on a *Bruker* SMART APEX II CCD diffractometer equipped with graphite monochromated MoKa 24 radiation ( $\lambda = 0.71073$  Å) by using  $\phi/\omega$  scan technique at room temperature. The 25 26 intensities were corrected for Lorentz and polarization effects as well as for empirical absorption based on multi-scan techniques; the structures was solved by direct methods 27 and refined by full-matrix least-squares fitting on  $F^2$  using SHEXL-97[16]. Absorption 28 corrections were applied using the multi-scan approach with the program SADABS [17]. 29 Indeed, the unit cell volume includes a large region of disordered nitrate and water 30 molecules which could not be modeled as well discrete atomic sites, but their 31

1 compositions can be confirmed by XPS, elemental analysis data, IR and TGA. Thus, they are included in the final formula. The formulation is supported by other chemical 2 3 analyses. The crystal structure analysis, however, is unambiguous in the context of connectivity. The core fragment of the ligand, consisting of the two C-H and two methyl 4 groups, is disordered over two alternative orientations. The disordered atoms were 5 subjected to a rigid bond restraint. Subject to these conditions the occupancies refined to 6 7 0.67(4) and 0.33(4). The nitrate ion located within the void space of the metal-ligand framework is highly disordered and/or incompatible with the tetragonal symmetry. It was 8 9 added to the structural model using a rigid model and disordered over four symmetry equivalent sites with each one quarter occupancy, and it was refined as disordered with 10 four water molecules. Table 1 shows crystallographic data of 1. Selected bond distances 11 and bond angles are listed in Table 2. CCDC: 972847. 12

# 13 Synthesis of complex 1

A mixture of Cu(NO<sub>3</sub>)<sub>2</sub> (0.1 mmol), bib (0.1 mmol), CH<sub>3</sub>OH (2 mL) and deionised water (10 mL) was placed in a Teflonlined stainless steel vessel, heated to 160 °C for 3 days under autogenous pressure, and then cooled to room temperature at a rate of 5 °C/h. Yellow crystals were obtained. The resulting crystals formed were filtered off, washed with water and dried in air.  $C_{28}H_{40}CuN_5O_7$  (622.19). Calcd: C, 54.05; H, 6.48; N, 11.26. Found C, 55.33; H, 6.20; N, 11.41. **IR** (KBr, cm<sup>-1</sup>): 3426(vs); 3118(m); 2219(m); 1620(m); 1492(s);1344(s);1259(vs); 730(vs). Raman: 1012(m); 1219(w); 1609(vs).

# 21 **Results and Discussion**

22 Compound 1 was synthesized in a solvent system composed of methanol (CH<sub>3</sub>OH). The 1 cannot be obtained under low temperature, the reaction used of the same reactant 23 24 process employed for the synthesis of 1 under 120 °C, which led to the formation of powder. Moreover, the pH value of the reaction solution does not play a role key in 25 determining the final products, although we have tried to adjust the pH (such as 6 and 7.5) 26 27 at different degrees. During the reaction process, the Cu(II) ions were reduced in situ to 28 form Cu(I). The XPS spectrum results (932.8 eV Cu(I) character) indicate that Cu(I) is present in the coordination polymer of 1 (Fig. S1). Compound 1 crystallizes in the 29 30 tetragonal crystal system with the space group P4/n. In the asymmetric unit there are one crystallographically independent Cu(I) centre, two bib linkers, one nitrate anion and four 31

water molecules. The Cu1 atom lies on the four fold axis (Fig. 1). The charge of the 1 2 cationic framework is balanced by the guest nitrate anions. In 1, each Cu(I) ion is 3 coordinated by four nitrogen atoms from four independent bib ligands (Fig. 1), in other words, the bib linkers connect Cu(I) centers in four directions, generating a 3-D porous 4 MOF along the c axis (Fig. 2a). The Cu(I) centers serve as 4-connected tetrahedral nodes 5 to result in a **dia** topology with a point symbol of  $(6_2, 6_2, 6_2, 6_2, 6_2, 6_2, 6_2)$  (Fig. 2b) [18]. The 6 7 spaciousness of the net leads to the interpenetration of four identical nets (Fig. 2c). Compound 1 exhibits a four-fold parallel interpenetrating array to minimize the big void 8 space and stabilize the framework. Viewed along the *a* axis, there are grid channels with 9 a diameter of 10.1×8.9 Å. The effective free volume of 1, calculated by PLATON 10 analysis, is 6.2 % (1778.3  $Å^3$  per unit) without consideration of the water molecules [19]. 11 Polymer 1 has an usual 4-fold interpenetrated 3-D architecture with helical channels (Fig. 12 3). To the best of our knowledge, complex 1 is the first representative of this kind of 13 4-fold interpenetrated framework with only bib ligand (Fig.4). 14

# 15 IR, Thermogravimetric Analyses and XRPD

As to FTIR spectra (Fig. S2), the compound shows a broad band centered around 3482 cm<sup>-1</sup> may be attributed to the O-H stretching frequency of the water molecules in **1**. The O-H stretching vibration for *Ic* appears as a broad band centered around 3500 cm<sup>-1</sup> [20]. The peak at around 1620 cm<sup>-1</sup> is assigned to the  $v(NO_3^-)$  asymmetric and symmetric stretching vibrations in **1**.

To study the stability of the coordination polymer, thermogravimetric analysis (TGA) 21 22 of complex 1 was performed (Fig. S3). Compound 1 shows three of weight loss steps. The first weight loss begins at 20 °C and is completed at 115 °C. The observed weight 23 24 loss of 12.3 % is corresponding to the loss of the four crystallization water molecules (calcd 11.6 %). The second weight loss occurs in the range 140-429 °C, which can be 25 attributed to the elimination of one bib organic ligand. Removal of all organic 26 components was completely by 429 °C, indicated by a further weight loss of 78.77% 27 28 (calcd 78.13 %), roughly consistent with expulsion of the bib and the nitrate molecules.

To confirm the phase purity of the compound, the original sample was characterized by X-ray powder diffraction (XRPD) at room temperature. The pattern that simulated from the single-crystal X-ray data of compound was in agreement with the observed

experimental pattern, as shown in Fig. S4. Heating of 1 to 120 °C for 4 h removes the 1 2 free water to form the "evacuated" framework is defined as 1'. The XRPD pattern of 1' is 3 not similar to that of compound 1. Moreover, the pale yellow color of sample 1 changed in the process to a greenish-gray color of sample 1', and crystals of 1' become brittle and 4 can easily be broken. We tried to collect the single crystal XRD data of 1', however, the 5 sample 1' diffracts much weaker than that original sample 1 and no usable SC XPD data 6 7 could be obtained. We attribute this feature of sample 1' to a stabilizing effect of the guest water molecules through strong hydrogen bonding interactions with the nitrate anion. 8 9 Loss of the water molecules also can be expected to lead to a more flexible and less rigid nature for the remaining structure, thus leading to weaker overall diffraction. 10

Organic-inorganic coordination polymers, especially those with d<sup>10</sup> metal centers, have 11 been investigated for their fluorescent properties and potential applications as 12 13 fluorescen-emitting materials, such as light-emitting diodes (LEDs) [21]. Therefore, the complex 1 was studied in the solid-state at room temperature (Fig. 5). Excitation of the 14 microcrystalline sample at 346 nm leads to the generation of fluorescent emission, with 15 the peak maxima occurring at 585 nm for 1. The spectrum of 1' is similar to that of 16 complex 1, but the intensity is weaker and the main peak of 1' is blue-shifted by about 28 17 nm compared to compound 1. The above luminescent phenomenon is presumably due to 18 the more rigid nature architecture of 1, when compared to dehydrated 1'. In the original 19 20 crystal, abundant lattice water molecules fill in the network and interact through weak forces such as hydrogen bonds with the framework lattice of 1. These weak forces do not 21 only stabilize the framework and enhance its rigid structure, but they also affect the 22 transfer of energy effectively from the bib to the metal center. Accordingly, some guest 23 24 molecules are removed from 1, in which undoubtedly decreasing the weak interactions. Therefore, the emission spectrum becomes weaker, and the main peak is shifted. 25 26 Moreover, this compound exhibits strong photoluminescence at room temperature and 27 may be suitable as a candidate of luminescent materials [22].

The fluorescence lifetime  $\tau$  values of **1** and **1'** are on the nanosecond timescale at room temperature, as shown in Fig.S3. The  $\chi^2$  values are found to be close to 1.0 in both compounds. Interestingly, the complexes **1** and **1'** have lifetimes in the range 4.2 ns for **1** and 2.8 ns for **1'**at the same excitation wavelength ( $\lambda_{em} = 346$  nm), respectively, as shown 1 in Fig. S5.

# 2 Gas sorption properties

3 From Fig. 6, it can be observed that the amount of CO<sub>2</sub> sorption rises gradually from  $P/P_0 = 0$  to 1.0. This is a Type I isotherm behavior typical for the microporous materials 4 but similar to Type II or Type III isotherms as defined by the IUPAC classification [23]. 5 This unusual sorption feature can be attributed to one of two reasons: on the one hand, 1 6 7 is a cation framework and its channels may be blocked by the large and immovable nitrate anions; on the other hand, the interaction between CO<sub>2</sub> molecules and the cation 8 framework is very weak. Comparison of the CO<sub>2</sub> sorption curve with the N<sub>2</sub> curve 9 indicates that the latter reason can exclude as the main cause of the weak adsorption of 10  $CO_2$  into the framework of 1. The high N<sub>2</sub> gas sorption amount shows 29 cm<sup>3</sup>(STP)/g at 11 P/P0 = 1.0 and 77 K, and exhibits no significant hysteresis between sorption and 12 13 desorption traces, indicating 1 to not be a microporous material [24].

14 To understand the solvent dependence of gas adsorption behavior in this MOF, grand 15 canonical Monte Carlo (GCMC) simulations using standard algorithms were performed to predict H<sub>2</sub> adsorption isotherms. The simulation cell consists of  $2 \times 2 \times 1$  unit cells of the 16 MOF. Periodic boundary conditions were applied in all three dimensions. For each state 17 point, the GCMC simulation consisted of  $1 \times 10^7$  steps to guarantee equilibration followed 18 by  $1 \times 10^7$  steps to sample the desired thermodynamic properties. H<sub>2</sub> and MOF interactions 19 20 are modeled by Lennard-Jones potential between all pairs of sites. GCMC simulations were performed at 77 K [25], in the pressure range p = 0-1000.0 KPa. From Figure 7 we 21 can see that H<sub>2</sub> uptake in this MOF containing solvent molecules is 10mmol/g at 77K 22 with 1000 kPa, but it is 45 mmol/g H<sub>2</sub> adsorption in MOF without solvent molecules. 23

24 In order to understand the reason that H<sub>2</sub> adsorption of MOF containing solvent molecules is lower than MOF without solvent molecules, we calculate the Connolly 25 Surfaces of MOF containing solvents and MOF without solvents, respectively. The 26 27 calculated results show that this MOF surface area is reduced significantly by solvent molecules from 734.83  $Å^2$  to 189.72  $Å^2$ . This conclusion can be confirmed by a 28 molecular calculation (See Table S1 and Fig. S6). This could suggest that upon 29 de-hydration, the molecular framework collapses. The XRD and TGA diagrams confirm 30 this hypothesis (Fig. S3 and Fig. S4). The decomposition of sample 1' starts over at 150 °. 31

CrystEngComm Accepted Manuscript

1 Thus, the sample **1'** shows little gas sorption at low pressure.

2 The bonding sites of  $H_2$  with MOF are given in Figure 8. From Figure 8(a), it can be seen that the first H<sub>2</sub> molecule is located at the centre of solvent molecules, and average 3 distance between H atom and O atom is 2.583 Å. The interaction between H<sub>2</sub> and MOF is 4 mainly van der waals energy about -0.318kcal/mol. As comparison, Figure 8(b) show that 5 the first H<sub>2</sub> molecule is absorbed by-CH<sub>3</sub> group of ligand, the nearest distance between H 6 atom and C atom is 2.854 Å. van der waals interaction (-0.204 kcal/mol) also is mainly 7 interaction between H<sub>2</sub> and MOF. The snapshot of the MOF with H<sub>2</sub> at 1000 kPa 8 pressures is shown in Figure 9. For framework containing solvent molecules, the negative 9 potential locates around solvent molecules and major H<sub>2</sub> close to solvents. But for 10 framework without solvent molecules, the negative potential spreads along edge of pores 11 12 and partial H<sub>2</sub> molecules are absorbed around ligands. Please note, metal Cu scarcely absorbs any H<sub>2</sub> whether MOF containing solvents or without solvents. In conclusion, the 13 solvent molecules in MOF reduce the surface area and negative potential ranges, leading 14 15 to a smaller gas absorbed amounts [26].

### 16 Conclusions

In summary, we have successfully synthesized a new 3D porous cation framework 17 constructed from a flexible N-donor ligand. It shows a four-fold interpenetrated 3D 18 19 framework with a dia-like topology. The compound exhibits strong photoluminescence at room temperature and may be suitable as a candidate as a luminescent materials. The  $H_2$ 20 adsorption isotherm of the dehydrated coordination framework of 1' was estimated by 21 22 Connolly's algorithm. We hope that the synthetic methods described herein will further facilitate the exploration of new types of multifunctional materials with interesting 23 properties, including the combination of porosity and luminescence. 24

In this work, we present a four-fold interpenetrated 3D framework with a **dia**-like topology. The luminescent property of sample 1 and dehydrated sample 1' was also explored.
