Accepted Manuscript

This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard Terms \& Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.

# Orthogonal halogen and hydrogen bonds involving a peptide bond model

#### Abstract

The peptide bond model $N$-methylacetamide self-assembles with a range of dihalotetrafluorobenzenes forming co-crystals that all show the occurrence of orthogonal hydrogen and hal10 ogen bonds.

Orthogonal self-assembly relies on the use of multiple interaction motifs applied in the same system to drive the assembly of different components. The specific and highly controllable interactions that are used do not influence each other's assembly pro${ }_{5}$ file and can be manipulated independently and simultaneously. ${ }^{1}$

In 2009, P. S. Ho and co-workers ${ }^{2}$ demonstrated, through a Protein Data Bank (PDB) survey, that in protein-ligand complexes hydrogen (HB) and halogen (XB) bonds ${ }^{3}$ occur orthogonally, both in terms of their geometric features and their chemical be20 haviour, when sharing the carbonyl oxygen atom of the peptide bond as common bond acceptor. Lately, we have demonstrated that HB and XB can successfully be combined in an orthogonal manner to drive the self-assembly of complex and functional supramolecular networks. ${ }^{4}$ In this latter case, the two interactions
25 did not share the same acceptor partner. Very recently, Bruce et al. successfully reproduced Ho's orthogonal motifs by using $N$ methylacetamide and $N$-methylbenzamide as peptide bond models with a selected number of iodinated XB-donors. ${ }^{5}$ However, in their hands $N$-methylacetamide decomposed to methylacetamide 30 and any attempt to get analogous motifs involving brominated donors failed.

In this communication, we demonstrate in small molecule selfassembly that HB and XB occur orthogonally on the same acceptor site in a very reliable and consistent manner also when bro-
35 minated XB-donors are used. We chose $N$-methylacetamide (NMA, 1) as the smallest molecule that mimics the peptide bond (-NH-C $=\mathrm{O}$ ) and thus the protein backbone. ${ }^{6}$ NMA effectively self-assembles with a range of dihalotetrafluorobenzenes resulting in co-crystals characterized by XBs occurring orthogonal to 40 the classical HB pattern that characterizes the homomeric assembly of NMA.

Very few examples of 'engineered' orthogonal XB and HB in the context of crystal engineering can be found in the Cambridge Structural Database (CSD), ${ }^{7}$ one exception being the iso45 nicotinamide-chloroacetic acid co-crystal ${ }^{8}$ (details about the CSD search are given in the Electronic Supplementary Information, ESI).

Scheme 1 Synthesis of $N$-methylacetamide (NMA, 1) co-crystals with 50 various dihalotetrafluorobenzenes ( $\mathrm{DXTFB}, \mathrm{X}=\mathrm{Br}$ or I ). The orthogonal angle $(\alpha)$ is defined as the angle between $\mathrm{XB}(\mathrm{C}-\mathrm{X} \cdots \mathrm{O}, \mathrm{X}=\mathrm{Br}$ or I$)$ and HB ( $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ ), i.e., $\angle \mathrm{X} \cdots \mathrm{O} \cdots \mathrm{N}$.

Our goal was to rationally design systems based on the orthogonal $\mathrm{HB} / \mathrm{XB}$ supramolecular synthon and verify its robustness for 55 use in crystal engineering. For this reason, NMA 1, affording the carbonyl oxygen acceptor site, was co-crystallized with several dihalotetrafluorobenzenes (DXTFBs), the XB-donors (1,2dibromotetrafluorobenzene (12DBrTFB, 2a), 1,3-dibromotetrafluorobenzene (13DBrTFB, 2b), 1,4-dibromotetrafluorobenzene ${ }_{60}$ (14DBrTFB, 2c), 1,2-diiodotetrafluorobenzene (12DITFB, 2d), 1,3-diiodotetrafluorobenzene (13DITFB, 2e), and 1,4-diiodotetrafluorobenzene (14DITFB, 2f)). The corresponding complexes 3a-f were obtained (Scheme 1).

We first re-determined the crystal structure of $\mathbf{1}$ at low temper65 ature by in situ cryo-crystallization using zone-melting procedure with an optical heating and crystallization device (OHCD). ${ }^{9}$ This was intended to get rid of static disorder that is found in the previously reported structures of NMA. ${ }^{10}$ A fully ordered crystal

${ }^{a}$ two symmetry independent molecules.

Fig. $1 \mathrm{~N}-\mathrm{H} \cdots \mathrm{O}$ HBs drive the formation of 1D infinite chains in the crystal packing of the homocrystal 1.
structure of 1 resulted in the Pnma space group. Classical N$\mathrm{H} \cdots \mathrm{O}(1.878(2) \AA)^{11}$ HBs link NMA molecules into infinite 1D ${ }_{10}$ chains running along the $a$ crystallographic axis (Fig. 1). The two interacting groups $\mathrm{N}-\mathrm{H}$ and $\mathrm{C}=\mathrm{O}$ are in trans conformation, this arrangement mimicking the molecular arrangement of the polypeptide backbone observed in $\beta$-sheet structures. ${ }^{12}$

DSC thermograms of 1:1 mixtures of $\mathbf{1}$ and $\mathbf{2 a - f}$ revealed that 15 both on cooling and on heating, the peaks for crystallization/melting of starting compounds were not observed, confirming quantitative co-crystal formations with the adopted tectons' ratio. New melting endotherms appeared at temperatures higher than the melting point of pure NMA $\left(12-20^{\circ} \mathrm{C}\right)$, except for $\mathbf{3 a}$ 20 that melted at $18{ }^{\circ} \mathrm{C}$ giving a quite sharp peak (Table 1). Interestingly, the melting points of $\mathbf{3 a}, \mathbf{b}, \mathbf{d}, \mathbf{e}$ are higher than, and of $\mathbf{3 c}$, f lower than, corresponding XB-donor tectons.

Good-quality single crystals 3a-f were reproducibly obtained from 1:1 ratios of the starting compounds and successfully ana${ }_{25}$ lysed by X-ray diffraction ( $\mathbf{3 a}$ and $\mathbf{3 b}$ are low-melting solids and required the OHCD method). All adducts show remarkable similarities in their supramolecular arrangements. The classical N $\mathrm{H} \cdots \mathrm{O}$ HBs observed in the crystal structure of pure NMA are preserved in co-crystals 3a-f and organize the NMA molecules into ${ }_{30}$ infinite 1D chains as in pure $1 . \mathrm{N}-\mathrm{H}^{\cdots} \mathrm{O}$ contacts span the range 1.831(4)-2.182(1) $\AA$ that do not differ much from the values seen in pure NMA, although in all the adducts the NMA molecule is disordered. Moreover, in all of the structures 3a-f the carbonyl O atom is involved in an additional XB involving at least one of the 35 two XB-donor sites of the used dihalotetrafluorobenzenes.

A distinctive feature of XB is its directionality. As expected, it has been observed in the C-X $\cdots \mathrm{O}$ angles of $\mathbf{3 a - f}$, which span the range $168.5^{\circ}-177.7^{\circ} . \mathrm{X} \cdots \mathrm{O}$ interaction distances are in the range $2.800(2)-2.871(4) \AA$ for $\mathrm{X}=\mathrm{Br}(\mathbf{3 a - c})$ and 2.706(2)-3.001(1) $\AA$
${ }_{40}$ for $\mathrm{X}=\mathrm{I}(\mathbf{3 d}-\mathbf{f})$, which correlates well to the calculated interaction energy curves for different complexes between halophenyl derivatives and NMA. ${ }^{13}$

Only one of the XB-donor sites of the DXTFBs in 3a-e is involved in XB with the carbonyl oxygen atom. Differently, in 3f,
${ }_{45}$ both of the iodine atoms of 14DITFB are halogen-bonded to the carbonyl oxygens of two NMA molecules belonging to two different hydrogen-bonded chains. In all of the six co-crystals, the oxygen atom of NMA is simultaneously involved in short HBs. Special attention during the analysis of the crystal structures has ${ }_{50}$ been given to the angle $\alpha$, which has been defined as the angle between XB and HB, $\angle \mathrm{X}-\mathrm{O}-\mathrm{N}$ as shown in Scheme 1. This angles in 3a-f vary in the range $77.9-98.5^{\circ}$, thus demonstrating the intrinsic tendency of HB and XB to occur orthogonally each other when sharing the same $\mathrm{sp}^{2} \mathrm{O}$ atom.

55
Fig. 2 Partial crystal packings showing how infinite 1D chains (horizontally positioned) formed by NMA via $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ HBs further interact with 14DITFB via $\mathrm{Br} \cdots \mathrm{O}$ XBs in $\mathbf{3 c}$ (top) and $\mathrm{I} \cdots \mathrm{O}$ XBs in $\mathbf{3 f}$ (bottom). The disorder on NMA molecule is omitted for clarity.
${ }_{60}$ Interestingly, while in $\mathbf{1}$ and $\mathbf{3 f}$ the $\mathrm{N}-\mathrm{H} \cdots \mathrm{O} \mathrm{HB}$ occurs perfectly in the carbonyl plane, in the structures 3a-e it assumes an out-of-plane arrangement deviating from the carbonyl plane by angles in the range $36.19^{\circ}-72.57^{\circ}$. The orthogonal XB occurs in the out-of-plane arrangement in all of the structures 3a-f, with the largest ${ }_{65}$ deviations in $\mathbf{3 c}$ and $\mathbf{3 f}$ where the positive $\sigma$-holes ${ }^{13}$ of bromine and iodine atoms enter the oxygen atom approximately in the equatorial region (the corresponding angles are $62.91^{\circ}$ in $\mathbf{3 c}$ and
$99.41^{\circ}$ in $\mathbf{3 f}$ (see ESI, Figure S4). Similar out-of-plane X $\cdots$ O interactions have been recently noted in protein-ligand complexes. ${ }^{14}$

The IR spectra of the co-crystals 3a-f essentially contain modi-
${ }_{5}$ fied vibrations of both the corresponding starting compounds and observed band shifts may give indication on how much the orthogonal HB and XB perturb the electron density of the carbonyl group. Pure NMA shows a broad $v_{\mathrm{C}=0}$ centred at $1634 \mathrm{~cm}^{-1}$. This band is consistently red-shifted in all of the co-crystals $\mathbf{3 a} \mathbf{- f}$, the ${ }_{10}$ largest shift $\left(27 \mathrm{~cm}^{-1}\right)$ being observed in $\mathbf{3 f}$. These red-shifts suggest that the simultaneous formation of HB and XB result in a reduced electron density on the carbonyl group with respect to the pure NMA. ${ }^{15}$ Interestingly, iodinated co-crystals show larger shifts than brominated co-crystals, as well as para derivatives ${ }_{15}$ show larger shifts than ortho and meta derivatives. The shifts of the $\mathrm{N}-\mathrm{H}$ stretching modes of the amide group (at $3290 \mathrm{~cm}^{-1}$ in pure 1) do not show any as clear trend. Moreover, no correlation has been found between the $\mathrm{N}-\mathrm{H}$ stretching values relative to the increasing energies of the XBs , as reflected in the $\mathrm{C}=\mathrm{O}$ stretch20 ing, demonstrating that the interactions are truly independent (see plot in the ESI).

In conclusion, we have reported the first halogen-bonded cocrystals formed by differently substituted ( $o, m$, and $p$ ) dihalotetrafluorobenzenes (halogen $=\mathrm{I}$ and Br ), functioning as halogen
25 bond-donor modules, and $N$-methylacetamide, a well-known peptide bond model. Six co-crystals were obtained and they all show geometrically orthogonal hydrogen and halogen bonds involving simultaneously the carbonyl oxygen atom. This demonstrates the great robustness of this orthogonal synthon, which occurs with a
${ }_{30} 100 \%$ supramolecular yield ${ }^{16}$ of the attempted co-crystals. The two interactions are also chemically orthogonal as the XBs formation does not alter the 1 D and hydrogen-bonded $\beta$-sheet mimetic chains typical of the homomeric assembly of N methylacetamide. A PDB survey performed by Ho et al. showed ${ }_{35}$ hydrogen and halogen bonds are orthogonal, both in terms of their geometric alignments and their chemical behaviour, when sharing the carbonyl oxygen atom of a peptide bond. Our results demonstrate this feature is not a peculiarity occurring only when biomacromolecules are involved, ${ }^{3}$ but it is a general feature of the 40 two interactions and it is probably inherent to their intrinsic chemical nature.

The reported results pave the way to a new design concept in orthogonal self-assembly and crystal engineering, and may also have important implications in other fields such as materials pro${ }_{45}$ cessing. As far as this field is concerned, amyloid and silk fibers are examples of ordered nanomaterials and they both feature robust $\beta$-sheet elements. The manipulation of the self-assembly and structural complexity of these nanomaterials during processing is still far from being completely understood. ${ }^{17}$ An approach based ${ }_{50}$ on the orthogonal interaction of $\beta$-sheets with halogen bonddonor mesogens may be particularly valuable. ${ }^{18}$ Current studies in our laboratory are addressing this issue and the results will be reported elsewhere.

This research was supported by MIUR (FIRB project "FLUO${ }_{55}$ RIMAGING" no. RBAP1183B5) and ERC (Starting Grant ERC-2012-StG_20111012 FOLDHALO, Grant Agreement Number 307108).

6 NMA has been widely used as a model for peptide and protein folding studies, which resulted in various spectroscopic and theoretical
95 investigations. In spite of its biological relevance, however, very few structural studies of NMA are known. The CSD, in fact, contains only three co-crystal structures of NMA with relevant organic compounds forming different hydrogen-bonded motifs (refcodes: IBOXOO, ANOPUP, ITYRMA10).
