Accepted Manuscript

This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard Terms \& Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.

# Biguanide and squaric acid as pH-dependent building blocks in crystal engineering 

Mihaela-Diana Șerb, ${ }^{a}$ Irmgard Kalf ${ }^{b}$ and Ulli Englert* ${ }^{b}$<br>Received (in XXX, XXX) Xth XXXXXXXXX 20XX, Accepted Xth XXXXXXXXX 20XX<br>${ }_{5}$ DOI: 10.1039/b000000x

In solutions containing biguanides and squaric acid, the pH value allows to control the outcome of crystallization. From $N, N$-dimethylbiguanide, $N$-phenylbiguanide and $N$ - $O$-tolylbiguanide 10 different salts have been obtained as a function of proton activity. The constituents in these ionic solids reflect the species present in solution: hydrogensquarate, still a strong acid, only occurs in crystals precipitated from 10 acidic medium, and biguanidinium monocations prevail in precipitates from basic solutions. Within these limitations, polymorphs and hydrates of different stoichiometry have been encountered. The pH of the crystallization medium also affects the nature of close contacts. The shortest hydrogen bonds in the crystalline solids do not occur between ions of opposite charge; rather, pH matching leads to close $\mathrm{O}-$ $\mathrm{H} \cdots \mathrm{O}$ contacts between squarate and hydrogensquarate anions which can only coexist at $\mathrm{pH}<4$.

## ${ }_{15}$ Introduction

Hydrogen bonds represent a particularly popular kind of intermolecular interaction. Their relevance for structural chemistry ${ }^{1,2}$ and biology ${ }^{3}$ stems from their wide occurrence among natural and synthetic compounds and from the broad range of energies they may cover. ${ }^{4}$ Hydrogen bonds are relevant with respect to reactivity, both in the fast developing field of organocatalysis ${ }^{5-7}$ and for biocatalysis by enzymes. ${ }^{8}$ Finally, hydrogen bonds offer an additional dimension to crystal engineering: At least those H atoms engaged in classical 25 hydrogen bonds may be re-arranged as a function of proton activity in the surrounding medium, and intermolecular contacts may thus be tuned by adjusting the pH . In this contribution, we systematically study the effect of pH changes on salt formation from alkyl or aryl biguanide cations and (hydrogen)squarate anions. Squaric acid is a strong organic acid, ${ }^{9}$ and biguanides are stronger bases than ammonia. ${ }^{10}$ Quite obviously, their neutral species cannot coexist. Full deprotonation of squaric acid and double protonation of biguanide, however, are associated with
similar $\mathrm{pK}_{\mathrm{a}}$ values; changes in the pH of the reaction mixture may 35 therefore bring about different protonation patterns. Scheme 1 compiles the pH -dependent composition of all solids which have been structurally characterized in the context of this study. Matulkova et al. ${ }^{11}$ have prepared biguanidinium salts of dicarboxylic acids with the intention to make novel materials for 40 second harmonic generation available. In 2001, Gilli and coworkers ${ }^{12}$ have reviewed the role of squaric acid and its anions as building blocks for hydrogen bonded crystals. Rao et al. investigated the crystalline salts formed by squaric acid and a series of amines without adjusting the proton activity of the ${ }_{45}$ resulting solutions. ${ }^{13}$ We only shortly mention alternative aspects of our reactands: Dimethylbiguanide ("Metformin") has found interest in medicinal chemistry ${ }^{14}$, and squarate $\mathrm{C}_{4} \mathrm{O}_{4}{ }^{2-}$ has been used in crystal engineering as an O donor ligand, in particular with respect to magnetic interactions. ${ }^{15-18}$

Scheme 1 Composition of salts based on biguanidinium cations and (hydrogen)squarate anions as a function of pH .

## Results and Discussion

The concentration of the alternative cationic species derived from 5 biguanide and of the anions hydrogensquarate and squarate obviously depends on the proton concentration in the reaction medium. Therefore, the pH of the solution can act as a tunable parameters in crystal engineering: Fully protonated dications and hydrogensquarate as building blocks can only exist in acidic 10 solution, whereas the corresponding monocationic species and squarate dianions prevale in basic medium. As may be anticipated from the pronounced differences in $\mathrm{pK}_{\mathrm{a}}$ values between acid and bases, ${ }^{19,20}$ all solids reported here are salts and no cocrystals have been observed. We will first shortly describe the composition and ${ }_{15}$ hydrogen bonds in the individual structures and then procede to a more synoptic section.

Dimethylbiguanidinium hydrochloride and squaric acid dissolve in water. The resulting strongly acidic aqueous solution ( $\mathrm{pH}<2$ )
20 affords crystals of $\mathbf{1 a}$. In this solid, fully protonated dications and hydrogensquarate mono-anions interact in layers in the (1-1 0) plane. (Fig. 1) Excellent crystals of 1a may be obtained in
impressive sizes: consequently, this compound has been characterized by high resolution X-ray diffraction and by neutron 25 diffraction. The complete characterization of $\mathbf{1 a}$ and a detailed discussion of its intra and intermolecular bonds based on an experimental charge density study have been published. ${ }^{21}$ We here briefly highlight the main features for comparison: Within the layers of crystalline 1a a large range of hydrogen bonds ${ }_{30}$ coexist. In addition to unexceptional classical $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ and $\mathrm{N}-$ $\mathrm{H} \cdots \mathrm{O}$ bonds and non-classical $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ contacts with hydrogen $\cdots$ acceptor distances close to the van der Waals limit, the compound features remarkably short (2.43 $\AA$ ) $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ bonds.

Fig. 1 Hydrogen-bonded layers in the crystal structure of 1a; H atoms bonded to C omitted.

In contrast to the layer structure above, the remaining derivatives 5 of dimethylbiguanide are 3D networks. In the salts obtained under less acidic conditions, i.e. in the range $2.6<\mathrm{pH}<4$, biguanidinium cations are still fully protonated but squarate rather than hydrogensquarate represents the anionic species. Two reaction products $\mathbf{1 b}$ and $\mathbf{1 c}$ are obtained in parallel. $\mathbf{1 b}$ is a 10 dihydrate with the composition $\mathrm{C}_{4} \mathrm{H}_{13} \mathrm{~N}_{5}{ }^{2+} \mathrm{C}_{4} \mathrm{O}_{4}{ }^{2-} \cdot 2 \mathrm{H}_{2} \mathrm{O}$; its single crystals are sufficiently stable for diffraction experiments. In contrast to larger crystals, ground material or the microcrystalline bulk reaction product readily release one equivalent of water and convert into a monohydrate. Although 15 this monohydrate has the same composition as $\mathbf{1 c}$ (see below), its powder pattern indicates a different structure. The second reaction product $\mathbf{1 c}$ is a monohydrate. $\mathbf{1 b}$ and $\mathbf{1 c}$ share the same building blocks, namely dimethylbiguanide dications, squarate dianions and solvent water, but the monohydrate 1c is ${ }_{20}$ considerably more stable towards with respect to desolvation: its experimental powder pattern shown in Fig. 2 and its elemental analysis (cf Experimental) match the expectation.
The dihydrate 1b and the monohydrate $\mathbf{1 c}$ differ significantly with respect to packing: Tab. 1 shows that $\mathrm{O}-\mathrm{H}^{\cdots} \mathrm{O}$ hydrogen ${ }_{25}$ bonds are significantly shorter than $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ interactions in the former solid whereas the opposite is observed in the latter. 1b adopts the higher density and overall space filling, and it features classical $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ contacts shorter than $3 \AA$ whereas in $\mathbf{1 c}$ all $\mathrm{N}-$ H hydrogen donors are engaged in bonds to oxygen acceptors.

Fig. 2 Experimental and simulated powder patterns for 1c at 293 K.

Symmetry operators for $\mathbf{1 b}$ : ${ }^{i}=2-x, 1-y,-1 / 2+z ; ;^{i i}=x, 1+y, z$;
35 Symmetry operators for $\mathbf{1 c}:{ }^{\text {i }}=-1+x,-1+y, z ;{ }^{\text {ii }}=-x,-1 / 2+y, 1-z ; ;^{i i i}=1-x,-$ $1 / 2+y, 1-z ;$ iv $=1-x, 1 / 2+y, 1-z ;$ Symmetry operators for $1 \mathrm{~d}:{ }^{i}=\mathrm{x}, 1+\mathrm{y}, \mathrm{z} ;{ }^{\mathrm{ii}}=1-\mathrm{x}, 1-\mathrm{y}, 1-\mathrm{z}$.

A visual comparison is also straightforward: Anions and hydrate 40 water molecules alone form layers in the ( 010 ) plane in $\mathbf{1 b}$ (Fig. 3 ) but only chains along the crystallographic $b$ axis in 1c (Fig. 4).

Fig. 3 Anions and hydrate water molecules form hydrogen-bonded layers in the crystal structure of $\mathbf{1 b}$.
${ }_{45}$ Together with the cations, a three-dimensional hydrogen bond network is formed in both $\mathbf{1 b}$ and $\mathbf{1 c}$.

Fig. 4 Anions and hydrate water molecules form hydrogen-bonded chains in the crystal structure of $\mathbf{1 c}$.

In basic media ( $\mathrm{pH}>7$ ), dimethylbiguanide exists as a monocation; as expected, the building block originating from squaric acid is fully deprotonated. The resulting compound $\mathbf{1 d}$ is an instable hydrate: In the crystal, the asymmetric unit contains a ${ }_{5} \mathrm{C}_{4} \mathrm{H}_{12} \mathrm{~N}_{5}{ }^{+}$cation and a water molecule in general position and half of a squarate dianion which is located on a crystallographic inversion center. With respect to H bonds, $1 d$ represents the only structure described in this work which features an $\mathrm{O}-\mathrm{H} \cdots \mathrm{N}$ contact. (Tab. 1) The only $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bond in the 10 asymmetric unit occurs between the water molecule and the squarate dianion and is relevant for the dimensionality of the resulting overall structure: When the hydrate water molecules are omitted as in Fig. 5, the remaining H bonds in 1d give raise to a layer structure.
15

Fig. 5 Layers in the crystal of 1d; the red circle indicates where two water molecules link consecutive layers.

Powder diffraction shows that solid 1d readily releases its hydrate 20 water at ambient temperature, resulting in a crystalline powder of unknown structure. In parallel, elemental analyses of bulk samples indicate a degree of hydration inferior to the one confirmed by single crystal X-ray diffraction.
In addition to dimethylbiguanide, we have included the aryl${ }_{25}$ substituted bases phenyl- and tolylbiguanide in our study. For reasons of solubility, their salts with squaric acid have been obtained in a solvent mixture water:ethanol (1:1). As a function of pH , two different compounds are accessible from phenylbiguanide and squaric acid. The rather complex solid 2a ${ }_{30}$ crystallizes from acidic medium ( $\mathrm{pH} \approx 2.9$ ): its asymmetric unit consists of a mono- and a diprotonated biguanidinium cation, of a hydrogensquarate and a squarate anion and of half a cocrystallized ethanol molecule which is disordered about a crystallographic center of inversion. We here anticipate that 2a is
35 the only solid in which the cosolvent rather than water is included in the crystal structure. The immediate neighborhood of a mononext to a dication in the same solid allows to study the structural consequences of protonation. (Fig 6)

${ }^{40}$ selected interatomic distances reflecting the protonation patterns: N2-C15 $=1.312(3), \mathrm{N} 2-\mathrm{C} 16=1.342(3), \mathrm{N} 7-\mathrm{C} 23=1.369(3), \mathrm{N} 7-\mathrm{C} 24=1.360(3)$ $\AA$.
${ }_{45}$ Due to the additional $N$ protonation, $\mathrm{N}-\mathrm{C}$ distances involving N7 are significantly longer than those associated with N2. Similarly, the only protonated out of eight O atoms in the squarate and hydrogensquarate subtends the longest $\mathrm{O}-\mathrm{C}$ bond. This hydroxyl group is engaged in a short classical $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ contact, with a ${ }_{50}$ donor $\cdots$ acceptor distance of $2.496(3) \AA$. Table 2 summarizes the most important hydrogen bonds in $\mathbf{2 a}$ and $\mathbf{2 b}$.
In basic solution, phenylbiguanide and squaric acid form salt $\mathbf{2 b}$, with two $\mathrm{C}_{8} \mathrm{H}_{12} \mathrm{~N}_{5}{ }^{+}$monocations and one $\mathrm{C}_{4} \mathrm{O}_{4}{ }^{2-}$ dianion per asymmetric unit. The two symmetrically independent cations ${ }_{55}$ adopt different conformations but are very similar with respect to bond distances.

In both phenylbiguanidinium squarates $\mathbf{2 a}$ and $\mathbf{2 b}$, the heteroatoms and with them all classical hydrogen bonds arrange in layers separated by largely unpolar sections filled by aryl ${ }_{65}$ substituents. Fig. 7 shows this situation for $\mathbf{2 b}$.

Fig. 7 In 2b, hydrophilic and hydrophobic layers alternate in direction of the $c$ axis.

As mentioned above, the structural characterization of the 5 reaction products between phenylbiguanide and squaric acid in acidic medium was straightforward and afforded reproducibly $\mathbf{2 a}$, both for single crystals and the bulk. A more challenging situation was encountered for the related tolybiguanide: The concomitant polymorphs 3a and 3b were obtained in variable 10 amount. In addition, we isolated crystals of the alternative reaction product 3c which, however, cannot be reproduced reliably.
3a and 3b are polymorphs in a strict sense ${ }^{22}$ with exactly the same degree of hydration and follow the composition $\mathrm{C}_{9} \mathrm{H}_{19} \mathrm{~N}_{5}{ }^{2+}$
${ }_{15} \mathrm{C}_{4} \mathrm{O}_{4}{ }^{2-} \cdot \mathrm{H}_{2} \mathrm{O}$. 3a crystallizes in space group $P 2_{1} / c$, with one dication and a water molecule in general position and two dianions on crystallographic inversion centers. 3b corresponds to a closely related but more complex and more uncommon solution of the packing problem, with three independent dications, three 20 water molecules and two independent dianions in general position and two dianions on crystallographic inversion centers, i.e. a total of 10 independent residues in space group $P-1$. Remarkably, all three symmetrically independent cationic residues in $\mathbf{3 b}$ are very similar with respect to conformation.
${ }_{25}$ Fig. 8 shows that both polymorphic forms 3a and 3b are present in a powder pattern of the bulk.

Fig. 8 Concomitant polymorphs 3a and 3b: Experimental powder pattern of the bulk and simulated patterns based on the single crystal data.

The polymorphs $\mathbf{3 a}$ and $\mathbf{3 b}$ are closely related with respect to packing. Both compounds are characterized by a similar shortest lattice parameter $a$; the $c$ parameter in 3a almost matches $b$ in $\mathbf{3 b}$, and the subtended angles are also related for both compounds, 35 with $\beta$ in $\mathbf{3 a} \approx\left(180^{\circ}-\gamma\right)$ in $\mathbf{3 b}$. This 2D relationship between the polymorphs might well be responsible for their concomitant formation and is visualized in the upper part of Fig. 9. The polymorphs differ with respect of the arrangement of the squarate anions (Fig. 9, bottom).

$3 a$

Fig. 9 Projections of the polymorphs $\mathbf{3 a}$ (left) and $\mathbf{3 b}$ (right); the upper part of the figures emphasizes the 2D relationship whereas the lower part highlights the different anion stacking.

The third alternative reaction product of tolylbiguanide and ${ }_{45}$ squaric acid at $\mathrm{pH}<4$, compound $\mathbf{3 c}$, is an anhydrate. This compound was obtained in several batches by the same synthetic procedure as the concomitant polymorphs 3a and $\mathbf{3 b}$, and the powder pattern showed that the bulk sample was phase pure. Despite our efforts, we have not been able to link the outcome of so the crystallization to an obvious external parameter such as temperature, speed of evaporation or slight reactand excess. Single crystal X-ray diffraction revealed that $\mathbf{3 c}$ contains di- and mono-cations as well as di- and mono-anions. The concomitant presence of both anionic species results in a short $\mathrm{O}-\mathrm{H}^{\cdots} \mathrm{O}$ ${ }_{55}$ interaction between a hydrogen squarate and a squarate, with a donor $\cdots$ acceptor distance of $2.5120(14) \AA$. Selected hydrogen
bonds for all tolybiguanidinium salts 3a-3d have been compiled in Table 3.

In both polymorphs 3a and 3b, dianions and dications represent the only charged constituents. Formal re-distribution of a proton 10 leads to the concomitant presence of all potential charged species in 3c. We may speculate that lattice energy might favour the former and efficient hydrogen bonds the latter alterntive.
In contrast to the complex outcome of the reaction between tolybiguanide and squaric acid in acid medium, a single and ${ }_{15}$ phase pure product is obtained from basic solutions: Compound 3d contains one $\mathrm{C}_{9} \mathrm{H}_{14} \mathrm{~N}_{5}{ }^{+}$cation and half of a $\mathrm{C}_{4} \mathrm{O}_{4}{ }^{2-}$ dianion in the asymmetric unit, analogous to the composition of the corresponding phenyl derivative $\mathbf{2 b}$. Fig. 10 shows that polar, hetero-atom containing and apolar layers of the tolyl residues 20 alternate in the packing of 3d, also similar to the situation in the corresponding phenyl derivative $\mathbf{2 b}$.

Fig. 10 Packing in 3d; the sequence of polar and apolar layers has been 25

The comparison between the individual structures 1a-3d allows to identify common trends. In the first place, it is no surprise that hydrogen bonds of different type can be associated with different strength - on average, $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ bonds are shorter and presumably ${ }_{30}$ stronger than $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ or $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ contacts. More specifically, the three shortest hydrogen bonds in the solids 1a, 2a and 3c (Tables 1-3) all involve hydrogensquarate as the donor; this moiety can only exist in acidic medium. In 1a, both partaking
residues are hydrogensquarate: the OH groups of one anion 35 interacts with an O atom of a neighbour, thus perfectly matching the $\mathrm{pK}_{\mathrm{a}}$ equalization principle. ${ }^{23}$ According to this concept, short $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ interactions may be expected between conjugate acidbase pairs. It is therefore not surprising that the $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ bonds in 1a are significantly shorter than the interactions in $2 \mathbf{2 a}$ and $\mathbf{3 c}$ 40 where the closest contacts occur between hydrogensquarate as donor and squarate dianions as acceptor species. Similar short hydrogen bonds between squarate and hydrogensquarate moieties have been described by Koleva et al. ${ }^{24,25}$
In agreement with the idea of charge assistance, ${ }^{26}$ the closest N ${ }_{45} \mathrm{H} \cdots \mathrm{O}$ interactions are observed between biguanidinium dications and squarate dianions and can be as short as 2.609 (2) A in 1c. A topological result refers to the dimensionality of the hydrogenbond systems: whenever present, hydrate water molecules are included as neutral species and are engaged with three or four ${ }_{50}$ classical hydrogen bonds in the corresponding crystal structures. In all these hydrates, i.e. in structures $\mathbf{1 b}, \mathbf{1 c}, \mathbf{1 d}, \mathbf{3 a}$ and $\mathbf{3 b}$, three-dimensional networks are encountered, whereas the anhydrates 1a, 2b, 3c and 3d and the ethanol solvate 2a consistently form two-dimensional hydrogen-bonded layers.

## ${ }_{55}$ Experimental

## Chemical and Reagents

All reagents were purchased from Sigma Aldrich and used as received. Elemental analyses were carried out on a Heraeus CHNO-Rapid apparatus. Powder X-ray diffraction (PXRD) ${ }_{60}$ patterns were recorded at the Institute of Inorganic Chemistry, RWTH Aachen University, using a Stoe Imageplate-detector IPPSD. Flat samples were measured in transmission using Cu-K $\alpha 1-$ radiation at ambient temperature. pH measurements were performed with a glass electrode; the pH of the solutions was ${ }_{65}$ adjusted using KOH or NaOH in water.

## Synthesis of the $\boldsymbol{N}, \boldsymbol{N}$-dimethylbiguanidinium salts ${ }^{27}$

$N, N$-dimethylbiguanidinium-bis(hydrogen squarate), 1a
497 mg ( 3 mmol ) dimethylbiguanide hydrochloride and 342 mg ( 3 mmol ) squaric acid were mixed in $40 \mathrm{~cm}^{3}$ water and then ${ }_{70}$ heated at $60^{\circ}-70^{\circ} \mathrm{C}$ until the solid is dissolved and then stirred for 30 min without heating. The resulting mixture was filtered and the pH of the solution was measured ( $\mathrm{pH}=1.85$ ). Colourless crystals were obtained from the filtrate by evaporation at room temperature.
${ }_{75} \mathrm{C}_{12} \mathrm{H}_{15} \mathrm{~N}_{5} \mathrm{O}_{8}=\left(\mathrm{C}_{4} \mathrm{H}_{13} \mathrm{~N}_{5}\right)^{2+}, 2\left(\mathrm{C}_{4} \mathrm{HO}_{4}\right)^{-} ; \mathrm{MW}=357.28 \mathrm{~g} / \mathrm{mol}: \mathrm{mp}$ $205^{\circ} \mathrm{C}$. Anal. Found: H, 3.9; C, 40.8; N, 19.8; Calc. H, 4.2; C, 40.3; N, 19.6.
$N, N$-dimethylbiguanidinium-squarate dihydrate, $\mathbf{1 b}$ and $N$, ${ }_{80} \mathrm{~N}$-dimethylbiguanidinium-squarate hydrate, 1c
The reaction mixture prepared as for $\mathbf{1 a}$ was filtered and the pH of the solution was adjusted to $2.6<\mathrm{pH}<4$. Colourless crystals of both reaction products $\mathbf{1 b}$ and $\mathbf{1 c}$ were obtained. 1b: $\mathrm{C}_{8} \mathrm{H}_{17} \mathrm{~N}_{5} \mathrm{O}_{6}=\left(\mathrm{C}_{4} \mathrm{H}_{13} \mathrm{~N}_{5}\right)^{2+},\left(\mathrm{C}_{4} \mathrm{O}_{4}\right)^{2-}, 2\left(\mathrm{H}_{2} \mathrm{O}\right) ; \mathrm{MW}=279.27$ ${ }_{85} \mathrm{~g} / \mathrm{mol}: \mathrm{mp} 205^{\circ} \mathrm{C}$.

1c: $\mathrm{C}_{8} \mathrm{H}_{15} \mathrm{~N}_{5} \mathrm{O}_{5}=\left(\mathrm{C}_{4} \mathrm{H}_{13} \mathrm{~N}_{5}\right)^{2+}$, $\left(\mathrm{C}_{4} \mathrm{O}_{4}\right)^{2-},\left(\mathrm{H}_{2} \mathrm{O}\right) ; \mathrm{MW}=261.25$ $\mathrm{g} / \mathrm{mol}: \mathrm{mp} 210^{\circ} \mathrm{C}$. Anal. Found H, 5.6; C, 36.4; N, 26.4; Calc. H, 5.8; C, 36.8; N, 26.8.

Alternatively, 1c may be synthesized by reaction of
dimethylbiguanidinium hydrochloride and $\mathrm{Ag}_{2} \mathrm{C}_{4} \mathrm{O}_{4} .{ }^{28}$ (2:1 molar ratio) in $60 \mathrm{mLCH} \mathrm{CN}_{3} \mathrm{CN}: \mathrm{H}_{2} \mathrm{O}$ (1:1). Solid AgCl is removed by filtration, the solvent mixture is evaporated, and the product recrystallized from water.
5
Monohydrogen-( $N, \quad N$-dimethylbiguanidinium)-hemisquarate hydrate, 1d
The reaction mixture prepared as for $\mathbf{1 a}$ was filtered and the pH of the solution was adjusted to $\mathrm{pH}>7$. Colourless crystals were ${ }_{10}$ obtained from the filtrate by evaporation at room temperature. $\mathrm{C}_{6} \mathrm{H}_{14} \mathrm{~N}_{5} \mathrm{O}_{3}=\left(\mathrm{C}_{4} \mathrm{H}_{12} \mathrm{~N}_{5}\right)^{+}, 1 / 2\left(\mathrm{C}_{4} \mathrm{O}_{4}\right)^{2-},\left(\mathrm{H}_{2} \mathrm{O}\right) ; \mathrm{MW}=204.22$ $\mathrm{g} / \mathrm{mol}: \mathrm{mp} 240^{\circ} \mathrm{C}$.

## Synthesis of the $\boldsymbol{N}-$ phenylbiguanidinium salts ${ }^{27}$

(Monohydrogen $-N$-phenylbiguanidinium)-( $N$-phenylbiguanidin ${ }_{15}$ ium) -(hydrogensquarate)-squarate ethanol solvate, 2a
600 mg ( 3.4 mmol ) phenylbiguanide and $392 \mathrm{mg}(3.4 \mathrm{mmol})$ squaric acid were mixed in $40 \mathrm{~cm}^{3}$ water: ethanol (1:1) and then heated at $60^{\circ}-70^{\circ} \mathrm{C}$ until the solid is dissolved and then stirred for 30 min without heating. The resulting mixture was filtered 20 and the pH of the solution was measured $(\mathrm{pH}=2.9)$. Colourless crystals were obtained from the filtrate by evaporation at room temperature.
$\mathrm{C}_{25} \mathrm{H}_{29} \mathrm{~N}_{10} \mathrm{O}_{8.5}=\left(\mathrm{C}_{8} \mathrm{H}_{12} \mathrm{~N}_{5}\right)^{+},\left(\mathrm{C}_{8} \mathrm{H}_{13} \mathrm{~N}_{5}\right)^{2+},\left(\mathrm{C}_{4} \mathrm{HO}_{4}\right)^{-},\left(\mathrm{C}_{4} \mathrm{O}_{4}\right)^{2-}$, $1 / 2\left(\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}\right)$; MW $=605.58 \mathrm{~g} / \mathrm{mol}: \mathrm{mp} 209^{\circ} \mathrm{C}$. Anal. Found H , 25 4.7; C, 49.5; N, 23.3; Calc. H, 4.8; C, 49.6; N, 23.1.

Bis-(monohydrogen- $N$-phenylbiguanidinium)-squarate, 2b The reaction mixture prepared as for $\mathbf{2 a}$ was filtered and the pH of the solution was adjusted to $\mathrm{pH}>5$. Colourless crystals were ${ }_{30}$ obtained from the filtrate by evaporation at room temperature. $\mathrm{C}_{20} \mathrm{H}_{24} \mathrm{~N}_{10} \mathrm{O}_{4}=2\left(\mathrm{C}_{8} \mathrm{H}_{12} \mathrm{~N}_{5}\right)^{+},\left(\mathrm{C}_{4} \mathrm{O}_{4}\right)^{2-} ; \mathrm{MW}=468.49 \mathrm{~g} / \mathrm{mol}: \mathrm{mp}$ $220^{\circ} \mathrm{C}$. Anal. Found H, 4.6; C, 50.9; N, 30.0; Calc. H, 5.2; C, 51.3; N, 29.9.

## Synthesis of the ortho-tolylbiguanidinium salts ${ }^{27}$

350 -Tolylbiguanidinium-squarate hydrate, 3a and 3b
500 mg ( 2.6 mmol ) tolylbiguanide and $300 \mathrm{mg}(2.6 \mathrm{mmol})$ squaric acid were mixed in $40 \mathrm{~cm}^{3}$ water:ethanol (1:1) and then heated at $60^{\circ}-70^{\circ} \mathrm{C}$ until the solid is dissolved and then the heating is stopped and stirred for 30 min . The resulting mixture
40 was filtered and the pH of the solution was measured ( $\mathrm{pH}<4$ ). Colourless crystals were obtained from the filtrate by evaporation at room temperature. 3a and 3b are polymorphs and obtained concomitantly.
$\mathrm{C}_{13} \mathrm{H}_{17} \mathrm{~N}_{5} \mathrm{O}_{5}=\left(\mathrm{C}_{9} \mathrm{H}_{15} \mathrm{~N}_{5}\right)^{2+},\left(\mathrm{C}_{4} \mathrm{O}_{4}\right)^{2-},\left(\mathrm{H}_{2} \mathrm{O}\right) ; \mathrm{MW}=323.32$
${ }_{45} \mathrm{~g} / \mathrm{mol}: \mathrm{mp} 211^{\circ} \mathrm{C}$. Anal. Found H, 5.0 ; C, 48.6 ; N: 21.2; Calc. H, 5.3; C, 48.3; N, 21.7.

Monohydrogen- $o$-tolylbiguanidinium)-( $o$-tolylbiguanidinium)-(hydrogensquarate)-squarate, 3c
${ }_{50}$ Under the conditions above, mostly mixtures of the polymorphs 3a and 3b form. In a serie of consecutive syntheses, however, the anhydrous compound 3c has been obtained instead. Despite the fact that in these occasions the product had formed in good yield and as a phase-pure solid, we have not been able to identify a
55 clear reason for this alternative outcome of the crystallization experiments.
$\mathrm{C}_{26} \mathrm{H}_{30} \mathrm{~N}_{10} \mathrm{O}_{8}=\left(\mathrm{C}_{9} \mathrm{H}_{15} \mathrm{~N}_{5}\right)^{2+},\left(\mathrm{C}_{9} \mathrm{H}_{14} \mathrm{~N}_{5}\right)^{+},\left(\mathrm{C}_{4} \mathrm{HO}_{4}\right)^{-},\left(\mathrm{C}_{4} \mathrm{O}_{4}\right)^{2-} ; \mathrm{MW}$
$=610.60 \mathrm{~g} / \mathrm{mol}: \mathrm{mp} 192^{\circ} \mathrm{C}$. Anal. Found H, 5.0; C, 51.1; N, 23.1; Calc. H, 5.0; C, 51.1; N, 22.9.
${ }_{6} 6$
Monohydrogen-( $o$-tolylbiguanidinium)- hemisquarate, 3d
The reaction mixture prepared as for $\mathbf{3 a} / \mathbf{3} \mathbf{b}$ was filtered and the pH of the solution was adjusted to $\mathrm{pH}>7$. Colourless crystals were obtained from the filtrate by evaporation at room ${ }_{65}$ temperature.
$\mathrm{C}_{11} \mathrm{H}_{14} \mathrm{~N}_{5} \mathrm{O}_{2}=\left(\mathrm{C}_{9} \mathrm{H}_{14} \mathrm{~N}_{5}\right)^{+}, 1 / 2\left(\mathrm{C}_{4} \mathrm{O}_{4}\right)^{2-} ; \mathrm{MW}=248.27 \mathrm{~g} / \mathrm{mol}: \mathrm{mp}$ $245^{\circ} \mathrm{C}$. Anal. Found H, 5.5; C, 53.2; N, 28.1; Calc. H, 5.7; C, 53.2; N, 28.2.

## Single Crystal Structure Determinations

${ }_{70}$ All solids 1a-3d are colourless; with the exception of the hydrates $\mathbf{1 b}$ and $\mathbf{1 d}$, their crystals or crystalline powders are stable for at least several days at ambient conditions. Intensity data sets were collected in $\omega$-scan mode on a Bruker D8 goniometer equipped with an APEX CCD detector using Mo $K \alpha$ 75 radiation $(\lambda=0.71073 \AA)$. An Oxford Cryosystems 700 controller was used to ensure temperature stability during data collection. The intensities were integrated with the help of the program SAINT ${ }^{29}$ and scaled by the multi-scan technique. ${ }^{30}$ Crystal data and information concerning data collection have been 80 documented in Tables 4 and 5.
The structures were solved with direct methods ${ }^{31}$ and refined using full-matrix least squares on $F^{2}$ (SHELXL97). ${ }^{31}$ For ordered residues, anisotropic displacement parameters were assigned to non- H atoms; hydrogen atoms attached to C were constrained to ${ }_{85}$ idealized geometry and their isotropic displacement parameters were constrained to multiples of their parent atoms. H atoms attached to N and O were obtained as local maxima of electron density in Fourier difference syntheses and refined isotropically using distance restraints; target values of 0.84(2) $\AA$ for $\mathrm{O}-\mathrm{H}$ and ${ }_{90} 0.90(2) \AA$ for $\mathrm{N}-\mathrm{H}$ bond distances were used.
In the crystal structure of $\mathbf{2 a}$, the ethanol molecule is disordered about a center of inversion; all atoms in this residue were assigned occupancy parameters of 0.5 and isotropic displacement parameters, and distance restraints were used to ensure a ${ }_{95}$ chemically reasonable intramolecular geometry. Most likely, this orientational disorder in the solvent contributes to a lower fraction of observed ( $\mathrm{I}<2 \sigma(\mathrm{I})$ ) intensity data.

In the crystal structure of $\mathbf{3 c}$, a tentative anisotropic refinement of 100 the non-H atoms in the tolyl moiety $\mathrm{C} 18-\mathrm{C} 24$ indicated disorder. The final structure model involved a majority and a minority conformer for this residue; the sum of their occupancies was restrained to unity, and the individual occupancies refined to $0.815(3)$ and $0.185(3)$. Similarity restraints were applied to the 105 alternative conformers, and only one overall isotropic displacement parameter was refined for all non-H atoms of the minority conformer.
In the absence of significant anomalous scattering, no absolute structures have been determined for the non-centrosymmetric 110 crystal structures $\mathbf{1 b}$ and $\mathbf{1 c}$. The former belongs to crystal class mm 2 , and the absolute structure parameter only determines the orientation of the sample crystal; the latter compound represents a conglomerate.
Refinement results have been compiled in Tables 4 and 5. ${ }_{5}$ Packing coefficients were calculated with PLATON ${ }^{32}$; in the case
of disordered compounds, only the majority conformers were
taken into account.

## Conclusions

The outcome of crystallization experiments in the system biguanide - squaric acid depends on the pH of the medium in more than one aspect. A very obvious relationship links the ${ }_{s}$ proton concentration and the $\mathrm{pK}_{\mathrm{a}}$ of species potentially available for crystallization: substantial concentrations of hydrogensquarate anions and diprotonated biguanidinium cations are only encountered in acidic solutions. Shortest intermolecular interactions are influenced by pH , too: $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ contacts are
10 ubiquitous but cover a wide range in which charge-assisted interactions turn out shortest. $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds only occur under conditions of partial squarate protonation, i.e. at pH $<4$. These interactions are doubtlessly strong: with respect to apparent overall charges, they have to overcompensate the repulsion between the anionic species squarate and hydrogensquarate. A more detailed analysis concerning the electrostatics of similar anion $\cdots$ anion interactions has combined database searches and computational methods. ${ }^{33}$ The relevance of $\mathrm{pK}_{\mathrm{a}}$ matching ${ }^{23}$ for directing aggregation via hydrogen bonds has 20 been emphasized by Krische and coworkers; ${ }^{34}$ in this sense, the shortest hydrogen bonds between anions in our organic salts are really predictable!
In the crystal structures of the arylbiguanides $2 \mathbf{a}$ and $\mathbf{3 c}$, the additional co-existence of conjugated acids and bases not only in ${ }_{25}$ the anionic but also in the cationic part underlines how flexible the reaction partners may adapt to the crystallization conditions.
