This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
Photoelectrochemical Reduction of Aqueous Protons With a CuO|CuBi$_2$O$_4$ Heterojunction Under Visible Light Irradiation

Hyun S. Park,$^a$ Chong-Yong Lee,$^a$ and Erwin Reisner$^{a, d}$

A p-type heterojunction photoelectrode consisting of platinumized CuBi$_2$O$_4$ layered on a CuO film was prepared. The CuO|CuBi$_2$O$_4$|Pt electrode photo-generates H$_2$ in pH neutral aqueous solution during visible light irradiation and exhibits a substantially enhanced photocurrent compared to CuO|Pt and CuBi$_2$O$_4$|Pt electrodes. Reduced electron-hole recombination by the band offsets in the heterostructure is responsible for the improved photoelectrochemical performance of CuO|CuBi$_2$O$_4$ with a small band-gap of approximately 1.5 eV.

The development of an efficient, stable, and scalable photocatalyst for the conversion of solar energy into chemical energy is a major goal to address the energy challenge of this century. Photolysis of water into H$_2$ and O$_2$ on semiconductors has been studied for decades,$^1$ and current effort focuses on the discovery of small band-gap photocatalysts with high activity during visible light irradiation.

Theoretically, a band-gap of less than 1.8 eV would allow for a photon-to-H$_2$ conversion efficiency of more than 20%.$^{2, 3}$ A common strategy to achieve high efficiency is pairing a small band-gap photocathode for H$_2$ production with a semiconductor photoanode with complementary light absorption for water oxidation.$^{4, 5}$ Beyond efficiency, the semiconductor electrodes must also be made of inexpensive materials, easy to fabricate and display long-term stability in aqueous electrolyte solution.$^6$

Despite a large number of encouraging n-type photoanodes being available,$^{7-11}$ there are only a few promising candidates for efficient p-type photocathodes for the H$_2$ evolution reaction (HER). Many p-type semiconductors, e.g., p-doped Si,$^{12}$ Cu$_2$O,$^{13, 15}$ InP,$^{16}$ Cu$_2$ZnSnS$_4,$$^{17}$ Cu$_{n}$Ga$_{3-n}$Se$_{2},^{18}$ WSe$_2,$$^{19}$ CuRhO$_2,$$^{20}$ CuO,$^{21}$ and CuBi$_2$O$_4,$$^{22, 24}$ have been discussed for the photoelectrochemical (PEC) HER using solar energy. However, these photocathodes have currently restricted utility due to their high cost and/or rapid photodecomposition in aqueous solution.

CuBi$_2$O$_4$ is a natural mineral semiconductor with a tetragonal structure, which is (photo-)chemically unstable in acidic and pH neutral aqueous solution.$^{22, 23}$ Despite the attractive band-gap size of approximately 1.5 to 1.8 eV of the p-type semiconductor, there is only a limited number of studies where CuBi$_2$O$_4$ was employed as a photoelectrocatalyst.$^{22-24}$ CuO is another attractive and promising p-type semiconductor with a small band-gap.$^{26, 27}$ It has a conduction band position suitable for HER and has been used as coating on TiO$_2$ and CuO for visible light absorption and to improve the photochemical stability of the electrode, respectively.$^{28, 29}$ However, CuO and CuBi$_2$O$_4$ suffer from severe photodegradation in aqueous solution through photoreduction to metallic copper.$^{23}$

Herein, we report on the facile preparation of an inexpensive photocathode based on a CuO|CuBi$_2$O$_4$ heterojunction coated with Pt for visible light promoted HER in pH neutral aqueous electrolyte solution (Figure 1). The enhanced photocurrent is the result of improved electron-hole separation by utilizing the valence band offsets at the heterojunction interface and the Pt-layer enhanced the photo-stability of the CuO|CuBi$_2$O$_4$ heterojunction.

Figure 1. (A) Schematic energy diagram of the estimated band-edge positions of CuO|CuBi$_2$O$_4$|Pt heterojunction. (B) Powder X-ray diffraction patterns of CuO|CuBi$_2$O$_4$ heterojunction (α=CuBi$_2$O$_4$, PDF#48-1886; β=CuO, PDF#44-0706; and γ=FTO). Inset in (B) shows an SEM image of CuO|CuBi$_2$O$_4$ electrode surface.

CuO, CuBi$_2$O$_4$ and CuO|CuBi$_2$O$_4$ thin film electrodes were prepared by drop-casting the precursor solution (Cu(NO$_3$)$_2$ and Bi(NO$_3$)$_3$ in ethylene glycol) onto fluorine-doped tin oxide (FTO)-coated glass followed by heat treatment at 500 °C in air (see Electronic Supporting Information for experimental details and characterization). X-ray diffraction patterns show monoclinic CuO (PDF#44-0706) and Kusachite tetragonal CuBi$_2$O$_4$ (PDF#48-1886) without secondary phase formation in the homo-layered and heterostructured thin film electrodes (Figure 1 and S1). The crystal size observed by scanning electron microscopy (SEM) was...
approximately 100 nm for the FTO/CuO and FTO/CuO/CuBiO$_4$ heterojunction films, whereas a smooth surface was observed for the FTO/CuBiO$_4$ film (Figure 1 and S2). The FTO/CuO/CuBiO$_4$ heterojunction film shows a porous structure similar to that of FTO/CuO with a film thickness of about 300 nm as shown in the cross section image in Figure S2.

The photocactivity of the Pt-free electrodes was first studied by linear sweep voltammetry (LSV) and chronoamperometry (CA) at 0.2 V vs. normal hydrogen electrode (NHE) in a pH 6.8 aqueous solution (Figures S3 and S4). An AM 1.5G solar light irradiator with a UV-vis light intensity of 100 mW cm$^{-2}$ was employed. As expected, FTO/CuO, FTO/CuBiO$_4$, and FTO/CuO/CuBiO$_4$ showed poor photoactivity due to the absorption band gap of CuO only approximately 100 mV more positive potential compared to FTO/CuO (Figure S3). The positive onset potential of the FTO/CuBiO$_4$ electrode indicates a more positive flat-band or valence band edge potential of FTO/CuBiO$_4$ in agreement with previous reports in the literature.\textsuperscript{23, 30} Mott-Schottky plot analysis resulted in a flat-band potential of CuO and CuBiO$_4$ of 0.69±0.01 V and 0.81±0.03 V vs. NHE in neutral aqueous electrolyte solution (Figure S5), respectively, which is in agreement with the onset potentials in the LSV measurements.

PEC experiments with the FTO/CuO, FTO/CuBiO$_4$ and FTO/CuO/CuBiO$_4$ heterojunction electrodes in acetonitrile solution in the presence of an electron acceptor, ethyl viologen diperoxide (EV$^2$), were subsequently performed to avoid photodegradation in water with the bare metal oxide electrodes (Figures S6 and S7).\textsuperscript{24,30} The photocurrent measured under these conditions did not contain any background current from electrode photodecomposition and was therefore smaller than in the aqueous solution. Consequently, the FTO/CuO and FTO/CuBiO$_4$ electrodes show stable photocurrent without noticeable photodegradation in acetonitrile solution (Figure S7). The steady-state photocurrent measured by CA was only approximately 30% of the transient photocurrent for all electrodes measured by LSV and the large transient behavior, including peak-shaped photocurrent response in the LSV, indicates significant surface recombination at the photocathodes and visible light absorption by EV$^+$ formed at the electrode surface.\textsuperscript{18} Investigation of systematic surface passivation would be an efficient method to further reduce the recombination rate at surface defects and leading to an enhanced photocurrent.

The effect of different amounts of the Cu-based semiconductors deposited on FTO on the photocurrent was also studied in acetonitrile with EV$^2$ for each electrode (Figure S7). The optimized amount of metal ions was 2.2, 0.45, and 2.20±0.45 µmol cm$^{-2}$ for CuO, CuBiO$_4$, and CuO/CuBiO$_4$, respectively, used for electrode preparations in further experiments (cross-section images and film thickness are shown in Figure S2). Thicker films resulted in a decreased photocurrent response or physical instability.

The CuO/CuBiO$_4$ heterojunction displayed a substantially higher photocurrent in LSV and CA measurements than the homo-layered FTO/CuO or FTO/CuBiO$_4$ electrodes (Figure 2, S6, S7, and S8). For example, a three times higher photocurrent was obtained with the CuO/CuBiO$_4$ heterojunction for EV$^2$ reduction than with the homolayered electrodes at –0.45 V vs. NHE (Figure S7).

The higher photocurrent results from better electron-hole separation in the CuO/CuBiO$_4$ heterojunction than in CuO or CuBiO$_4$ for the following reasons: the photocurrent at FTO/CuO or FTO/CuBiO$_4$ was not limited by light absorption (thickness dependence in Figure S7D) and not hindered by the reaction kinetics for EV$^2$ reduction.\textsuperscript{39} The gradual increase of photocurrent observed at the CuO/CuBiO$_4$ heterojunction during CA can be assigned to a structural changes at the CuO and CuBiO$_4$ interface (Figure S7C and S9).\textsuperscript{32}

The Pt electrocatalyst was then photo-deposited on the electrodes from an aqueous K$_3$PtCl$_4$ solution (see ESI and Figure S10) in order to enhance the activity and stability of the photocathodes in aqueous electrolyte solution during illumination.\textsuperscript{33-35}

![Figure 2](image-url)
The valence band offsets or internal electric field given in the heterojunction indicates that enhanced electron-hole separation can occur in the heterostructured electrode of CuO and CuBi₂O₄. The heterojunction of FTO/CuO/CuBi₂O₄/Pt generates at least twice the photocurrent of homo-layered FTO/CuO/Pt or FTO/CuBi₂O₄/Pt electrodes due to the reduction of electron-hole recombination by the band offsets provided in the heterostructure. In contrast, a deteriorating effect was observed with an inverted heterojunction, i.e., FTO/CuBi₂O₄/CuO. With this electrode, a reduced photocurrent results from the deep valence band of CuBi₂O₄ and the resulting trapping of holes and increased electron-hole recombination at the interfaces between the CuBi₂O₄ and CuO layers (Figure S13).

H₂ generation at the photocathodes was confirmed by electrochemical detection of H₂ (Figure S14): A Pt ultramicroelectrode (UME) with a diameter of 100 μm with an applied potential of -0.3 V for H₂ oxidation was placed near (at an estimated distance of approximately 500 μm) the FTO/CuO/CuBi₂O₄/Pt electrode to detect H₂ during back-side irradiation of the photocathode (see Experimental Section in ESI for details). Thereby, H₂ diffuses from the photodecay to the Pt UME and the H₂ oxidation current at the latter is proportional to the H₂ evolved at the former electrode. Note that the FTO/CuO/CuBi₂O₄/Pt electrode has a small electrode area and was largely covered by an insulating epoxy resin resulting in a small current in Figure S14. A H₂ oxidation current was observed at the Pt UME upon irradiation of the FTO/CuO/CuBi₂O₄/Pt electrode. The electrooxidation current at Pt demonstrates H₂ evolution at the photocathode.

The photocathodest Pt on the heterojunction facilitates the reaction kinetics for HER and fewer photocatalyzed electrons are consumed for the electrode decomposition reactions shown in Eqs. 1 and 2. We note that H₂ was only detected at the Pt UME with the FTO/CuO/CuBi₂O₄/Pt photocathode, but not at FTO/CuO/CuBi₂O₄ without Pt, where the photocurrents are mainly due to photodecomposition of the heterojunction electrodes. Previously, photodecomposition of photocatalyst layers, e.g., Ru and Pt on p-WSe₂ for HER, or Co-Pt on Ba-doped Ta₅N₅ for OER, were used to fabricate the protective layers to reduce the photodecomposition reactions and to utilize electrons and holes primarily for HER and OER.

\text{CuO} + \text{H}_2\text{O} + 2e^- &\rightarrow 2\text{Cu} + 2\text{OH}^- \quad (E^\circ = 0.07 \text{V vs. NHE}) \quad (2)
\end{align*}
\]

Incident photon to current conversion efficiencies (IPCE) of FTO/CuO/CuBi₂O₄/Pt with UV-vis absorption spectra shown in Figure 3 indicate an excellent visible light response of the heterojunction electrode (see ESI for details). The heterojunction electrode shows maximum IPCE of 60% at 0 V for high-energy photon absorption, and shows a visible response at the wavelength up to 850 nm. The effective band-gap size of FTO/CuO/CuBi₂O₄/Pt electrode is therefore approximately 1.5 eV based on IPCE measurements. In addition, integration of the photocurrent over the wavelength from the IPCE measurements in Figure 3A further confirmed the efficient visible light harvesting of the heterojunction electrode (Figure 3B). Figure 3B shows the wavelength dependent photocurrent produced by absorbed photons. More than 80% of the photocurrent was generated by visible light irradiation with wavelength longer than 420 nm. The visible light response of the heterojunction in LSVs is also shown in Figure S15. IPCE values at various applied potentials in Figure S16 show that the photocatalysis enhancement in the heterojunction electrode appeared under monochromatic irradiation agrees well with the visible light response in Figure 2. Note that the beam intensities used for IPCE measurements indicated in Figure 3A were different from the AM 1.5 irradiance, which can affect IPCE values.†

In summary, a CuO/CuBi₂O₄/Pt electrode for visible light driven H₂ evolution in aqueous electrolyte solution is reported. The novel heterojunction electrode structure reduces charge recombination, has a narrow band-gap of approximately 1.5 eV and can be stabilized in water with a suitable electrocatalyst layer. CuO/CuBi₂O₄ is also easy to assemble, does not contain prohibitively expensive materials and is therefore a promising candidate for visible absorption and charge separation in solar-to-fuel conversion devices with theoretical efficiencies of more than 20%. CuO and CuBi₂O₄ form an excellent heterojunction pair, which more than doubles the photoactivity compared to the corresponding monolayer electrodes.

To further increase the performance and stability of photoelectrodes in aqueous solution and replacement of Pt by inexpensive electrocatalysts is currently in progress in our laboratory.
