This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
Superior catalytic performance of Ce$_{1-x}$Bi$_x$O$_{2-\delta}$ solid solution and Au/Ce$_{1-x}$Bi$_x$O$_{2-\delta}$ for 5-hydroxymethylfurfural conversion in alkaline aqueous solution

DOI: 10.1039/h000000x

Porous Bi-doped ceria (Ce$_{1-x}$Bi$_x$O$_{2-\delta}$ solid solution) was prepared by the easy citrate method, and then used as supporting material for Au nanoparticles (NPs) obtained by deposition-precipitation method. In the presence of O$_2$, Ce$_{1-x}$Bi$_x$O$_{2-\delta}$ (0.08\(\leq\)x\(\leq\)0.5) efficiently catalyzed the conversion of 5-hydroxymethylfurfural (HMF) to 5-hydroxyethyl-2-furancarboxylic acid (HFCA) and 2,5-bishydroxymethylfuran (BHMF) in alkaline aqueous solution, without degradation of HMF. The excellent catalytic activity was attributed to the oxygen activation and hydride transfer enhanced by Bi doping and the large amount of oxygen vacancies. After Au NPs supported on Ce$_{1-x}$Bi$_x$O$_{2-\delta}$ (x\(\leq\)0.2), the presence of Au$^{2+}$ facilitated the activation of the C-H bond in hydroxymethyl group and then the production of 2,5-furandicarboxylic acid (FDCA) as end-product, inhibiting the generation of BHMF.

Introduction

With the continuous consumption of fossil resources such as oil and natural gas, it is of great importance to exploit and utilize renewable, abundant biomass preparation of bulk and fine chemicals. 1-3 5-hydroxymethylfurfural (HMF), which can be obtained from dehydration of glucose or fructose, 4, 5 is a compelling platform chemical for the production of 2,5-diformylfuran (DFF), 2,5-bishydroxymethylfuran (BHMF), 5-hydroxymethyl-2-furancarboxylic acid (HFCA) and 2,5-furandicarboxylic acid (FDCA). DFF and BHMF have been regarded as promising monomers for preparing resins, polymers and fine chemicals. 6, 7 HFCA serves not only as a monomer in various polyesters, 8 but also as a starting material for synthesis of FDCA. The presence of two carboxylic groups in FDCA makes it a potential polymer building block which could substitute petro-based terephthalic, isophthalic, and adipic acids. 9

Many efforts have been made over the past two decades in converting HMF to those more valuable derivatives. 10-14 Vinke et al. firstly reported the oxidation of aqueous HMF into FDCA in near-quantitative yield under basic reaction conditions with a Pt/Al$_2$O$_3$ catalyst at 60 °C. 15 Verdeguer et al. demonstrated that high pH was needed to produce FDCA over PtPb/C catalysts and hydroxide base was more effective than carbonate base, which was applicable to the production of HFCA. 16 Davis et al. have shown that the activity of Au catalysts for HMF oxidation was an order of magnitude higher than either Pt or Pd catalysts, but the selectivity to FDCA was much lower than that over the Pt and Pd catalysts. 17

The oxidation of HMF comprises of an aldehyde oxidation and an alcohol oxidation (Scheme 1). 18-21 Davis et al. 17 recently elucidated the reaction mechanism that water, rather than O$_2$, was the source of oxygen atoms inserted into the products by using isotopically-labeled $^{18}$O$_2$ and H$_2^{18}$O. The aldehyde side chain of HMF firstly underwent rapid reversible hydration to a geminal diol intermediate in alkaline aqueous solution. Then, the dehydrogenation of the geminal diol was facilitated by the noble metal catalyst and hydroxide ions. This process produced HFCA and deposited two electrons on the catalyst. The following oxidation of the alcohol group to form 5-formyl-2-furancarboxylic acid (FFCA) was the rate limiting step, as the activation of the C-H bond in the hydroxymethyl group strongly depended on the abilities of catalyst, such as transferring hydride, depositing two additional electrons and interacting with O$_2$. O$_2$ was essential for these oxidation processes and played an indirect role via removing the electrons deposited on the catalyst and being reduced to peroxide and hydroxide ions. The aldehyde group of FFCA underwent the same oxidation process in the conversion of HMF to HFCA. Finally, FDCA was obtained.

Scheme 1 Oxidation of HMF to FDCA.

Scheme 2 Cannizzaro reaction of HMF.
Notably, although alkaline conditions are favorable for the oxidation of HMF, other competitive reactions could occur at the same time, such as degradation and Cannizzaro reaction of HMF. The Cannizzaro reaction is base-induced disproportionation reaction of an aldehyde lacking a hydrogen atom at an α-position to the carbonyl group. In alkaline medium, one molecule of the aldehyde hydrates to a geminal diol and acts as a hydride donor while the other functions as an acceptor, resulting in a carboxylic acid salt and an alcohol product, respectively. The hydride transfer was the principal component of this redox process. The conversion of HMF to HFCA and BHMFF simultaneously via Cannizzaro reaction is of great value (Scheme 2), circumventing using oxidant (for HFCA) or reductor (for BHMFF). Recently, Subbiah et al. have investigated the reaction in NaOH aqueous solution. High yields of HFCA and BHMFF were obtained when the reactions were conducted at 0 °C for 1 h and then room temperature for certain hours. However, these processes needed a quite long reaction time, such as 18 h, without the presence of catalyst. In addition, the yields were very low at 60 °C even reacted for 24 h, which was due to serious degradation of HMF under basic conditions at higher temperature.

Nanoparticulate CeO_2 with a high external-to-internal atom ratio has a large number of surface oxygen vacancies and defects, which could disperse and stabilize gold nanoparticles (NPs). To reach nearly 99% yield of FDCA, the reaction time for Au NPs on nanoparticulate CeO_2 was half for the Au on non-nanometric CeO_2. Reductive pretreatment of the Au/ CeO_2 was shown to efficiently increase the catalytic activity, because it increased the amount of Ce^{3+} and oxygen vacancies. The increased Ce^{3+} and oxygen vacancies have shown great importance in transferring hydride and activating O_2 during catalytic oxidation of alcohols in former reports. Corrana et al. proposed that Ce^{3+} centers (Lewis acid sites and stoichiometric oxidation sites of CeO_2) and Au^{+} species of Au/ CeO_2 could readily accept a hydride from C-H bond in alcohol or in the corresponding alkoxide to form Ce-H and Au-H, with the formation of carbonyl compound at the same time. The oxygen vacancies of ceria could activate O_2 and form cerium-bridged superoxide (Ce-OOC•••) species which subsequently evolved into cerium hydroperoxide by hydrogen abstraction from Au-H. The cerium hydroperoxide then interacted with Ce-H, producing H_2O and recovering to Ce^{4+} centers. Au-H donated H and changed back to the initial Au^{+} species. Without Au^{+}, the catalytic cycle could not complete.

As discussed above, for ceria base catalyst, increasing the amount of oxygen vacancies would improve the catalytic activity towards HMF conversion. It is favorable for O_2 activation and hydride transfer from HMF (or the geminal diol intermediate) to catalyst. The doping with low-value metal cations to substitute Ce in the CeO_2 lattice would drive the formation of a stable O-deficient bulk fluorite-type structure to maintain charge conservation. Ce^{3+} centers would increase with the creation of oxygen vacancies. Cubic δ-Bi_2O_3 has an atomic configuration of C-type rare earth sesquioxide, which is similar to CeO_2. As an oxide ionic conductor, it could release oxygen at low temperature, leading that the Bi-doped CeO_2 has a higher low-temperature redox activity towards CeO_2.

Glaeser et al. have also indicated that the lone pair electrons of Bi^{3+} was the active site for O_2 activation, and oxide ion of Bi-O-M could help the hydrogen transfer from reaction substrate to the catalyst in selective oxidation. Thus, the Bi-doped CeO_2 may serve as an admirable catalyst for Cannizzaro reaction of HMF or excellent support of Au NPs for HMF oxidation.

Herein, a series of Ce_{1-x}Bi_{x}O_2.4 (x≤0.5) were synthesized by the easy citrate method and used as supports for gold NPs obtained via a deposition-precipitation method. Ce_{1-x}Bi_{x}O_2.8 and Au/Ce_{1-x}Bi_{x}O_2.8 were all examined in HMF conversion in alkaline aqueous solution. Interestingly, in the presence of O_2, Ce_{1-x}Bi_{x}O_2.8 (0.08≤x≤0.5) could catalyze HMF transform into HFCA and BHMFF at 65 °C without degradation of HMF. Au/Ce_{1-x}Bi_{x}O_2.8 (0.08≤x≤0.2) catalysts showed significantly improved catalytic activities towards HMF oxidation to FDCA compared to Au/CeO_2. To the best of our knowledge, it is the first report about the Cannizzaro reaction of HMF catalyzed by non-precious metal oxide in eco-friendly aqueous solution.

**Experimental**

**Chemicals and Characterization**

All the reagents were used as received without further purification. HMF (98%), HFCA, 5-Formyl-2-furancarboxylic Acid (FFCA, 98%), FDCA (97%) were obtained from J & K Co. Ltd (Beijing, China). Ce(NO_3)_3·6H_2O, Bi(NO_3)_3·5H_2O were purchased from Aladdin Chemicals Co. Ltd (Shanghai, China). Concentrated HNO_3, concentrated H_2SO_4, KOH, citric acid monohydrate were purchased from Beijing Chemicals Co. Ltd (Beijing, China). HAuCl_4·4H_2O was obtained from Shanghai Chemical reagent Co. Ltd (Shanghai, China).

The powder X-ray diffraction (XRD) patterns were carried out on a Bruker D8 Advance X-ray diffractometer using a Cu Ka radiation source (λ = 1.5406 Å). Scanning electron microscopy (SEM) was performed on a field emission Hitachi S-4800 instrument. Transmission electron microscopy (TEM) was performed using a FEI Tecnai G2 S-Twin instrument with a field emission gun operating at 200 kV. Raman spectra were collected through a Renishaw 2000 model confocal microscopy Raman spectrometer with a CCD detector and a holographic notch filter (Renishaw Ltd., Gloucestershire, U.K.) at ambient conditions, using the radiation of 514.5 nm. H_2-TPR experiment was conducted on a self-made chemisorption instrument equipped with a thermal conductivity detector (TCD). 50 mg of fresh samples were loaded into a quartz reactor at room temperature and reduced in a flowing 5% H_2/Ar mixed gas with a heating rate of 10 °C/min. The effluent gas was analyzed with the TCD. The nitrogen adsorption-desorption isotherms of the samples were measured with a Autosorb-iQ-Station-1 instrument at 77 K after pretreated at 473 K for 10 h under high vacuum. The specific surface areas were determined by Brunauer-Emmett-Teller (BET) equation. Elemental contents were measured by ICP-OES (iCAP 6300 Thermo Scientific USA). X-ray photoelectron spectroscopy (XPS) spectra were obtained on a VG Thermo ESCALAB 250 spectrometer operated at 120 W. All the binding energies were calibrated using the Ce^{4+}(3d^34f^15p^0) (u) signal at 916.6 eV to remove surface charging effects. Liquid state ^1H NMR spectra were recorded at 298 K on a Bruker Avance 300 NMR spectrometer.
Catalyst preparation

A series of Ce$_{1-x}$Bi$_x$O$_{2.5}$ mixed oxides with $x = 0, 0.05, 0.1, 0.125, 0.15, 0.2, 0.5$ were prepared by the citrate acid method. In a typical synthesis, stoichiometric amounts of Bi(NO$_3$)$_3$·5H$_2$O and Ce(NO$_3$)$_3$·6H$_2$O (Bi + Ce = 0.1 mol) were mixed in an appropriate concentration of nitric acid solution to obtain a clear solution. Citric acid monohydrate was then added to the mixture (metal cation to ligand molar ratio was 1:2). The as-prepared solution was heated on a hot plate at 200 °C under stirring.

Continuous heating process turned this solution to white (without Bi) or yellow gel, which was afterwards combusted with flame and yielded highly spongy and uneven color bulk particles. Finally, the precursors were calcined at 500 °C for 2 h to obtain Ce$_{1-x}$Bi$_x$O$_{2.5}$ mixed oxides. The color of Bi-doped ceria samples was yellow and deepened with increasing the amount of Bi doping (Fig. S1).

Gold NPs were deposited on Ce$_{1-x}$Bi$_x$O$_{2.5}$ via a deposition-precipitation method. 15 ml of 8 mM HAuCl$_4$ aqueous solution was sampled into a round bottom flask, 1.0 M KOH was then added dropwise to the stirred solution until the pH value was readjusted to 10. The suspension kept stirring for another 2 h, for 2 days. The Au/Ce$_{1-x}$Bi$_x$O$_{2.5}$ samples were calcined at 200 °C for 2.5 h before use.

HMF conversion in alkaline aqueous solution

The aqueous phase catalytic conversion of HMF was carried out in a 50 ml autoclave with PTFE liner and equipped with a magnetic stirrer. In a typical experiment, 6 ml of the reactant solution (0.15 M HMF and 0.6 M NaOH) was added to the reactor along with the appropriate amount of catalyst. The reactor was purged for 3 times with O$_2$ and then pressurized at 1.0 MPa. Timing was started once the reactor was placed in a preheated oil bath pot under stirring. After reacting for a certain time, the samples were centrifuged, diluted with deionized H$_2$O for 50 times and acidified with sulfuric acid. The resulted solution was filtered and calibration of FDCA, HFCA, FFCA and HMF were determined by injecting known concentrations.

$^a$ Calculated by BJH method from desorption branch. $^b$ Estimated by single point adsorption at relative pressure of 0.99.

The as-prepared samples were proved to be porous material. SEM images shown in Fig. S2 illustrated the presence of macropores larger than 50 nm. The nitrogen physisorption analysis results of the Ce$_{1-x}$Bi$_x$O$_{2.5}$ (x = 0, 0.05, 0.1, 0.2, 0.5) samples are summarized in Table 1. The adsorption isotherms and pore size distribution curves are presented in Fig. S3. The adsorption-desorption isotherms of all the samples showed type IV isotherm with a hysteresis loop, indicating that these samples were mainly in the mesoporous range of 2-50 nm. The pore size was centered at about 3.8 nm. In addition, the specific surface area of CeO$_2$ was calculated to be 117.90 m$^2$/g and the total pore volume was 0.35 cm$^3$/g which both decreased with increasing the amount of Bi doping.

Results and discussion

Fig. 1 XRD patterns of (a) CeO$_2$, (b) Ce$_{0.95}$Bi$_{0.05}$O$_{2.5}$, (c) Ce$_{0.9}$Bi$_{0.1}$O$_{2.5}$, (d) Ce$_{0.8}$Bi$_{0.2}$O$_{2.5}$ and (e) Ce$_{0.6}$Bi$_{0.4}$O$_{2.5}$ (inset: XRD of samples scanned at low speed).

The powder XRD patterns of Ce$_{1-x}$Bi$_x$O$_{2.5}$ (x≤0.2) samples showed in Fig. 1 demonstrate that only peaks attributed to a cubic fluorite structure of CeO$_2$ (JCPDS 34-0394) were observed and no other phase was detected. Compared with the pure CeO$_2$ sample, the diffraction peaks of the Bi-doped samples were slightly shifted to lower angle (inset of Fig. 1), indicating the expansion of the unit cell of CeO$_2$. This variation could be intelligibly ascribed to Ce$^{4+}$ with ionic radius of 0.97 Å partially replaced by Bi$^{3+}$ (1.17 Å) and the formation of solid solution. For Ce$_{0.5}$Bi$_{0.5}$O$_{2.5}$ sample, in addition to the low value-shifted peaks of CeO$_2$, peaks located at around 28.0° and 46.2° appeared, which could be ascribed to Bi$_2$O$_3$ (JCPDS 65-1209).

Fig. 2 Raman spectra of (a) CeO$_2$, (b) Ce$_{0.95}$Bi$_{0.05}$O$_{2.5}$, (c) Ce$_{0.9}$Bi$_{0.1}$O$_{2.5}$, (d) Ce$_{0.8}$Bi$_{0.2}$O$_{2.5}$ and (e) Ce$_{0.6}$Bi$_{0.4}$O$_{2.5}$.
Raman spectra of Ce_{1-x}Bi_{2-x}O_{3−δ} (x = 0, 0.05, 0.1, 0.2, 0.5) samples are presented in Fig. 2. The main peak at ca. 460 cm\(^{-1}\) was assigned to the F\(_{2g}\) mode vibration of CeO\(_2\) cubic fluorite structure.\(^{34}\) The Bi doped samples also showed two peaks at ca. 520 and 580 cm\(^{-1}\), which could be indexed to the presence of Bi\(^{3+}\) ions\(^{35}\) and oxygen vacancies generated as charge compensating defects\(^{36}\), respectively. For CeO\(_2\), a very weak peak at ca. 580 cm\(^{-1}\) was also observed, suggesting the presence of a small number of oxygen vacancies in CeO\(_2\) possibly caused in the violent and rough citrate-method process. It was obvious that the oxygen vacancies peak enhanced significantly after Bi doping, implying the increase of the amount of oxygen vacancies. When the relative content of Bi reached to 20 mol\%, a characteristic peak of Bi\(_2\)O\(_3\) appeared.\(^{37,38}\) The Bi\(_2\)O\(_3\) phase could not be detected by XRD analysis, suggesting that Bi\(_2\)O\(_3\) species should be in a low content and disperse well in Ce\(_{0.8}\)Bi\(_{0.2}\)O\(_2.8\).

In order to figure out the low-temperature redox activity of Ce\(_{1-x}\)Bi\(_{2-x}\)O\(_{3−δ}\), the reduction profiles of the samples were taken and the results are shown in Fig. 3. The H\(_2\) reduction maximum of Bi-doped samples occurred at 200–400 °C associated with the reduction of Ce\(^{4+}\) and Bi\(^{3+}\). The temperature was much lower than that of pure ceria, indicating the more reducible property of the Bi-doped samples. Higher oxygen release capacity of the Bi-doped samples could also be found, as the peak area increased with the amount of Bi doping. The results also indicated that the amount of the stoichiometric oxidation sites showed the similar behavior.

HMF conversion in alkaline aqueous solution was carried out with or without Ce\(_{1-x}\)Bi\(_{2-x}\)O\(_{3−δ}\) samples. The conversion of HMF and the yields of FDCA and HFCA that determined by HPLC analysis are listed in Table 2. As we knew, HMF was prone to degrade in alkaline aqueous solution, especially at high temperature. The red-brown solution obtained with the formation of by-products such as levulinic and formic acids.\(^{39}\) When Ce\(_{0.8}\)Bi\(_{0.2}\O_{2.8}\) (x = 0, 0.05) or no catalyst was added into the reaction system, the resulted reaction solutions after 1 h at 65 °C were red-brown with low yields of HFCA (Table 2, entries 1-3). However, with Ce\(_{x}\)Bi\(_{2−δ}\)O\(_{3}\) (0.08≤x≤0.5) in the reaction system, the resultant solutions were nearly colorless and the yields of HFCA were high (Table 2, entries 4-9). The results may be ascribed to the presence of abundant stoichiometric oxidation sites in Ce\(_{1−x}\)Bi\(_{2−δ}\)O\(_{3}\) (0.08≤x≤0.5).

To further explain the results, following experiments were performed. After reacted over CeO\(_2\) or Ce\(_{0.875}\)Bi\(_{0.125}\)O\(_{2.8}\) for 1h, the reaction solution was centrifuged. The obtained supernatant was reacted for another hour by using Au/Ce\(_{0.875}\)Bi\(_{0.125}\)O\(_{3}\) catalyst at the same conditions. Interestingly, the Ce\(_{0.875}\)Bi\(_{0.125}\)O\(_{2.8}\) system obtained 90% yield of FDCA and 10% yield of HFCA (Table 2, entry 6) while CeO\(_2\) just did a total 28% yield of FDCA and HFCA (Table 2, entry 2). Obviously, there was no degradation of HMF occurred with the presence of Ce\(_{0.875}\)Bi\(_{0.125}\)O\(_{2.8}\) in alkaline aqueous solution. The product undetected by HPLC analysis after 1 h over Ce\(_{0.875}\)Bi\(_{0.125}\)O\(_{2.8}\) was sought to BHMF. BHMF was the Cannizzaro reaction product\(^{13,17}\) and did not respond to UV\(^{39}\) (Table 2, entry 6). \(^{1}H\) NMR analysis also proved it (Fig. S4).

Then, the BHMF yields of these reactions were determined by gas chromatography-mass spectrometry (GC-MS) analysis after extracting the resulted reaction solutions by ethyl ether (Fig. S5). The results are also listed in Table 2.

\(^{a}\) General conditions: 0.15 M HMF solution in 0.6 M NaOH (6 ml), 0.1 g Ce\(_{0.875}\)Bi\(_{0.125}\)O\(_{2.8}\), 65 °C, 1.0 MPa O\(_2\). \(^{b}\) Conversion or product yield determined by HPLC after reacted for 1 h. \(^{c}\) Reaction autoclave was sealed after all the Reaction autoclave was sealed after all the
Under air or 1.0 MPa Ar atmosphere and otherwise the same conditions, reactions with CeO$_{0.875}$Bi$_{0.125}$O$_{2-δ}$ all resulted in low yields of HFCA (Table 3, entries 2, 3). These results indicated that O$_2$ was essential for HMF conversion catalyzed by CeO$_{0.875}$Bi$_{0.125}$O$_{2-δ}$ and there was strong interaction between Ce$_{1-x}$Bi$_x$O$_{2-δ}$ (0.08≤x≤0.5) and O$_2$. Other M-doped Ce$_{0.875}$M$_{0.125}$O$_{2-δ}$ (M = Y, La, Mn, Fe) samples were also examined in HMF conversion in the presence of O$_2$ (1.0 MPa). They all resulted in serious degradation of HMF with low yields of HFCA (Table. S1). It implied that the Bi-doped CeO$_2$ was unique for O$_2$ activation during HMF conversion in alkaline aqueous solution.

16% yield of HFCA was obtained under 1.0 MPa Ar atmosphere (Table 3, entry 3). It meant that CeO$_{0.875}$Bi$_{0.125}$O$_{2-δ}$ contained large amount of stoichiometric oxidation sites and acted as oxygen donor.\(^{40-42}\) When gaseous oxygen was introduced into the reaction system, CeO$_{0.875}$Bi$_{0.125}$O$_{2-δ}$ could act as an oxygen pump, releasing and adsorbing oxygen through a redox process. The redox process involved the variation of the two oxidation states of Ce (III and IV) and related to the exotic highly reductive Bi\(^{3+}\). The lone pair electrons of Bi\(^{3+}\) and the large amount of oxygen vacancies facilitated the O\(_2\) adsorption and dissociation during this process.\(^{27-29}\) As a result, the present O$_2$ in the reaction system replenished the consumed lattice oxygen (mainly oxide ions of the Bi-O-Ce linkages) in CeO$_{0.875}$Bi$_{0.125}$O$_{2-δ}$ and avoided Ce$_{0.875}$Bi$_{0.125}$O$_{2-δ}$ from deactivating, leading to the transformation of HMF via Cannizzaro reaction without degradation.\(^{41,44}\)

Subbiah et al.\(^{13}\) have shown that Cannizzaro reaction of HMF could be performed at room temperature without catalyst in NaOH aqueous solution. The reaction time was up to 18 h. The 43% yield of BHMF and 44% yield of HFCA that obtained under the optimized reaction conditions suggested more than 10% degradation of HMF. Moreover, serious decomposition of HMF was found at higher temperature (60 °C), producing only 22% total yield of BHMF and HFCA even after 24 h. In our system, however, the degradation of HMF was inhibited even at 65 °C, and the reaction time for 100% conversion of HMF reduced greatly to less than 1 h with the presence of Ce$_{0.875}$Bi$_{0.125}$O$_{2-δ}$ (0.08≤x≤0.5) and 1.0 MPa O$_2$ in the reaction system simultaneously (Table 2, entries 4-9). The reaction efficiency was improved greatly.

A 66% total yield of carboxylic acid products (more than 50%) was obtained under 1.0 MPa O$_2$ pressure over CeO$_{0.875}$Bi$_{0.125}$O$_{2-δ}$ catalyst (Table 2, entry 6). It implied that Cannizzaro reaction and oxidation of HMF proceeded simultaneously. The geminal diol intermediate was firstly formed via rapid reversible hydration of HMF,\(^{17,40}\) then, it partly reacted with the aldehyde moiety of HMF and obtained the Cannizzaro reaction products HFCA and BHMF equivalently.\(^{13,19}\) While others underwent the oxidation of geminal diol or hydroxymethyl group and yielded HFCA or FDCA. The electrons generated during the oxidation reaction were removed by molecular oxygen, and the catalytic cycle closed.\(^{17}\) The oxidation and Cannizzaro reaction both involved hydride transfer from geminal diol and the Bi-doped CeO$_2$ showed unique performance towards the reaction system.

Therefore, we summarized that the presence of Bi-O-Ce linkages and Ce\(^{3+}\) centers, together with the lone pair electrons of Bi\(^{3+}\) and large amount of oxygen vacancies, assisted CeO$_{0.875}$Bi$_{0.125}$O$_{2-δ}$ transferring hydride and activating O$_2$, thereby catalysing the reaction.\(^{25,29}\)

As shown in Fig. 4, HMF was quickly transformed to products with the presence of O$_2$ and CeO$_{0.875}$Bi$_{0.125}$O$_{2-δ}$. A 97% conversion of HMF was achieved only after 20 min. It further indicated the excellent properties of CeO$_{0.875}$Bi$_{0.125}$O$_{2-δ}$ towards activating oxygen and transferring hydride. CeO$_{0.875}$Bi$_{0.125}$O$_{2-δ}$ itself showed weak ability to activate the cleavage of C-H bond in hydroxymethyl group, resulted in the low yield of FDCA and large amount of BHMF.

$^a$ General conditions: 0.15 M HMF solution in 0.6 M NaOH (6 ml), Au : HMF = 6.67×10$^{-3}$ mol/mol, 65 °C, 1.0 MPa O$_2$.\(^{11}\) From ICP analysis.\(^{13}\) Conversion or product yield determined by HPLC after reacted for 1 h.

All the Au/Ce$_{1-x}$Bi$_{2-δ}$ samples showed similar Au loading around 1 wt%. To compare their catalytic activities, they were all applied in the oxidation of HMF at the same reaction conditions for 1 h. The results are listed in Table 4. Besides Au/Ce$_{1-x}$Bi$_{2-δ}$, all the Bi-doped catalysts displayed higher FDCA yield with respect to Au/CeO$_2$. Au/Ce$_{1-x}$Bi$_{2-δ}$ (0.08≤x≤0.2) catalysts were active enough to catalyze the oxidation of HMF to HFCA and FDCA (Table 4, entries 3-7). However, Au/Ce$_{1-x}$Bi$_{2-δ}$ (x = 0, 0.05) catalysts resulted in not only low yields of FDCA but also the production of some degradation products (Table 4, entries 1, 2). The favorable catalytic activity of Au/Ce$_{1-x}$Bi$_{2-δ}$ (0.08≤x≤0.2) towards HMF oxidation was attributed to the presence of Au$^{3+}$ and Bi doping. Au$^{3+}$ in the Au/Ce$_{1-x}$Bi$_{2-δ}$ catalysts assisted the oxidation of alcohol, including turning alcohol into metal-alcoholate intermediate and activating the C-H bond. Besides, in the whole oxidation process, the hydride transferred from C-H bond could not only combine with Ce$^{3+}$ and...
Au\textsuperscript{+}, but also with oxygen ions of Bi-O linkages and Ce\textsuperscript{2+}-O centers.\textsuperscript{16, 25, 45} The electrons generated during the hydride transfer were captured by Au clusters and the reducible Ce\textsubscript{1-\(x\)}Bi\textsubscript{2}O\textsubscript{4} support, and then released when the Au/Ce\textsubscript{1-\(x\)}Bi\textsubscript{2}O\textsubscript{4} interacted with molecular O\textsubscript{2}.\textsuperscript{17, 46} As the geminal diol intermediate was more easily oxidized, the Cannizzaro reaction was inhibited over Au/Ce\textsubscript{0.9}Bi\textsubscript{2}O\textsubscript{4.8} (x\textless 0.2) catalysts. Oxidation products HFCA and FDCA were yielded without the formation of BHMF. Based on the above analysis, the first two reaction processes are listed in Scheme 3.

![Scheme 3](image)

**Scheme 3** The first two reaction processes of HMF conversion in alkaline aqueous solution. CeBi represents Ce\textsubscript{0.1}Bi\textsubscript{2}O\textsubscript{4} (0.08\textless x\textless 0.5) and Au represents Au/Ce\textsubscript{0.1}Bi\textsubscript{2}O\textsubscript{4} (x\textless 0.2).

TEM images of Au/Ce\textsubscript{1-x}Bi\textsubscript{2}O\textsubscript{4} (x = 0.1, 0.5) after reacted for 1 h are shown in Fig. 5. Because of the low loading amount of Au and the low contrast between Au and ceria, Au particles were hardly detectable by TEM.\textsuperscript{47} Only a few nanocrystals with a size of about 4 nm were identified as the gold phase on Au/Ce\textsubscript{0.5}Bi\textsubscript{2}O\textsubscript{4} catalyst (Fig. 5a, b), and no Au particle was found on the Au/Ce\textsubscript{1-\(x\)}Bi\textsubscript{2}O\textsubscript{4} (x = 0, 0.2, 0.5) catalysts. XRD patterns of all the samples are shown in Fig. S6. No characteristic diffraction peak corresponding to gold (38.2°, 44.3°) was observed. Bi\textsubscript{2}O\textsubscript{3} phase was also found in the Au/Ce\textsubscript{0.5}Bi\textsubscript{0.5}O\textsubscript{2} sample by TEM (Fig. 5c).

Quantitative fitting of the Au (4f) peaks of Au/Ce\textsubscript{1-x}Bi\textsubscript{2}O\textsubscript{4} (x = 0, 0.1, 0.2, 0.5) catalysts after reacted for 1 h are shown in table 5 and Fig. S7. It is well documented in the literature that the electronic state of surface gold NPs depends on the size of gold NPs and the nature of supports, and always plays an important role in the oxidation reaction.\textsuperscript{48} For alcohol oxidation catalyzed by Au/Ce\textsubscript{0}, Au\textsuperscript{3+} was considered as the active site on Au clusters.\textsuperscript{23, 25, 46} There existed about 25% of Au\textsuperscript{3+} in Au/Ce\textsubscript{0.5}Bi\textsubscript{0.5}O\textsubscript{2} catalyst, which might be too low to afford the activation of the C-H bond in alcohol, and resulted in the low yield of FDCA (Table 4, entry 8). Here, we also noticed that after calcination at 200 °C for 2.5 h, the Au/Ce\textsubscript{1-x}Bi\textsubscript{2}O\textsubscript{4} (x\textless 0.15) samples turned to purple, while Au/Ce\textsubscript{0.9}Bi\textsubscript{0.1}O\textsubscript{2} was sap green and Au/Ce\textsubscript{0.9}Bi\textsubscript{0.1}O\textsubscript{2} was emerald. It implied the presence of different Au species in Au/Ce\textsubscript{1-x}Bi\textsubscript{2}O\textsubscript{4} catalysts. In addition, the color of these catalysts deepened after NaOH added into the reaction mixture, which was similar to a previous report.\textsuperscript{48}

The above results demonstrated that the Au/Ce\textsubscript{1-x}Bi\textsubscript{2}O\textsubscript{4} (0.08\textless x\textless 0.2) catalysts were preferable for HMF oxidation to FDCA. Au/Ce\textsubscript{0.5}Bi\textsubscript{0.5}O\textsubscript{2} was selected to further investigate the effect of the reaction parameters, such as amount of base, temperature, oxygen pressure, HMF/Au molar ratio and reaction time. The results are shown in Fig. S8-11.

![Fig. 6](image)

**Fig. 6** HMF conversion and product yields as a function of reaction time in the oxidation of HMF in aqueous solution over Au/Ce\textsubscript{0.5}Bi\textsubscript{0.5}O\textsubscript{2} catalyst (Au : HMF = 6.67×10\textsuperscript{2} mol/mol, 4 equiv. NaOH, 1.0 MPa O\textsubscript{2}, 65 °C; HMF: ■, FDCA: ●, HFFA: ▲, FFCA: ▲).

4 equiv. NaOH, 1.0 MPa O\textsubscript{2}, 65 °C and HMF/Au molar ratio 150 were chosen to study the effect of reaction time over Au/Ce\textsubscript{0.5}Bi\textsubscript{0.5}O\textsubscript{2} catalyst. As shown in Fig. 6, the aldehyde moiety of HMF was quickly oxidized to carboxylic acid at the initial stage of the reaction, 100% conversion of HMF and 95% yield of HFCA were achieved only after 10 min. That stressed the superiority of Ce\textsubscript{1-x}Bi\textsubscript{2}O\textsubscript{4} for HMF conversion. Subsequently, the amount of HFCA slowly decreased while the yield of FDCA increased. There only a little FFCA was detected within the first 45 min, indicating that the oxidation of alcohol group to aldehyde was the rate limiting step. It was identical with previous reports.\textsuperscript{15}
Catalysis recycling was also studied for the Au/Ce\textsubscript{0.8}Bi\textsubscript{0.2}O\textsubscript{2}\textdelta\textsuperscript{+} catalyst. After the catalyst was recovered by filtration, washed with water and dried at 60 °C, a new set of HMF oxidation experiments were carried out (Fig. 7). The presence and quantity of Au element in the filtrate was analyzed by ICP-OES analysis, thus excluding the hypothesis of Au leaching. The catalyst could be used for three times without much loss of activity under identical reaction conditions. The yield of FDCA was only 86% after the fourth use, but the solution after reaction was also colorless and there was almost no other by-product besides HFCAs. We could deem that increasing the reaction time would also result a >99% yield of FDCA. After using for three times, we found that large catalyst particles appeared. The decrease of the FDCA selectivity may be due to the agglomeration of the catalyst or the adsorption of organic molecules onto partial active sites of the catalyst.

Conclusions

In this work, a series of porous Bi-doped ceria were prepared by the easy citrate method. XRD and Raman analysis indicated that Ce\textsubscript{1−x}Bi\textsubscript{x}O\textsubscript{2−δ} solid solutions were obtained with large amount of oxygen vacancy defects. In the presence of O\textsubscript{2}, Ce\textsubscript{1−x}Bi\textsubscript{x}O\textsubscript{2−δ} (0.08≤x≤0.5) efficiently catalyzed HMF into BHMF and HFCAs in alkaline aqueous solution. Nearly completely conversion of HMF (97%) was reached only in 20 min at 65 °C and 1.0 MPa O\textsubscript{2} without degradation of HMF. The superior catalytic properties of Ce\textsubscript{1−x}Bi\textsubscript{x}O\textsubscript{2−δ} (0.08≤x≤0.5) were attributed to the specific Bi\textsuperscript{3+} doping. O\textsubscript{2} activation and hydride transfer were enhanced by the lone pair electrons of Bi\textsuperscript{3+} and the presence of Bi-O-Ce linkages together with large amount of Ce\textsuperscript{δ+} centers and oxygen vacancies. The presence of Au\textsuperscript{0} in the Au/Ce\textsubscript{1−x}Bi\textsubscript{x}O\textsubscript{2−δ} (≤0.2) catalysts assisted the oxidation of alcohol, especially the geminal diol intermediate, yielding FDCA as end-product without BHMF. >99% yield of FDCA was obtained after 2 h over Au/Ce\textsubscript{0.8}Bi\textsubscript{0.2}O\textsuperscript{2−δ} catalyst. Ce\textsubscript{1−x}Bi\textsubscript{x}O\textsubscript{2−δ} (0.08≤x≤0.5) may be also applicable for other Cannizzaro reactions with the presence of O\textsubscript{2}. Combined with other noble metals or metal oxides, Ce\textsubscript{1−x}Bi\textsubscript{x}O\textsubscript{2−δ} could activate the C-H bond in alcohol, leading the formation of active catalysts for HMF or other alcohol oxidation in alkaline aqueous solution.
