This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
Two new metal phosphite-oxalates, CN₅H₆·Co(H₂PO₃)(C₂O₄) (1) and (CN₅H₆)₂·Mn₂.₅(HPO₃)(C₂O₄)₂.₅(H₂O)·H₂O (2), have been prepared under solvent-free conditions. The two open-framework compounds have diamondoid and pillared-layered structures, respectively. Their photoluminescence and magnetic properties are also investigated.

Microporous and open-framework materials, such as zeolites and coordination polymers, have been extensively studied for their potential applications in catalysis, ion-exchange, gas storage, separation, and sensor technology. Recent developments show that new open-framework structures can be created by integrating both structural and compositional features of zeolite inorganic solids and coordination polymers. During the past years, great efforts have been focused on the synthesis of metal-phosphate-oxalate hybrid solids. In comparison, the inorganic-organic hybrid frameworks containing phosphite units have been rarely reported. It has been demonstrated that the replacement of phosphate groups by phosphite units can reduce the M–O–P connectivity and generate interrupted framework structures. A notable example is NTHU-13 with tunable pore sizes ranging from 24-merbered ring (24 MR) to 72 MR.

Crystalline open-framework compounds are usually prepared under hydrothermal or solvothermal conditions. A challenging goal in this research is to eliminate the safety concerns associated with high reaction pressure. One feasible strategy is the replacement of molecular solvents by ionic liquids. For example, Morris and co-workers have succeeded in the ionothermal syntheses of a number of new zeotype inorganic solids and metal-organic frameworks by using ionic liquids as both solvents and templates. The ionothermal reactions may take place at ambient pressure due to the negligible vapor pressure of ionic liquids. Another approach is to remove liquid solvents from porous material synthesis. It has been demonstrated that solvent-free mechanochemical synthesis is particularly effective for the preparation of porous coordination polymers. However, the products obtained by mechanochemical approach are usually microcrystalline powders, indicating that single-crystal X-ray diffraction cannot be used to determine their structures.

Inspired by the successful isolation of a open-framework inorganic solid NH₄[BPO₄F] in a solvent-free flux of H₂BO₃ and NH₄H₂PO₄, we expect that the combination of phosphorous acid (melting point: 73ºC) and oxalic acid (melting point: 102ºC) under solvent-free conditions may produce new inorganic-organic hybrid solids. During the course of such investigation, two open-framework metal phosphite-oxalates, CN₅H₆·Co(H₂PO₃)(C₂O₄) (1) and (CN₅H₆)₂·Mn₂.₅(HPO₃)(C₂O₄)₂.₅(H₂O)·H₂O (2), have been prepared in the presence of guanidinium cations as the structure-directing agents. Their structures were solved from single crystal X-ray diffraction data collected at room temperature on an Oxford Xcalibur diffractometer. Red crystals of compound 1 were obtained by heating a mixture of Co(OAc)₂·4H₂O, guanidinium carbonate, H₃PO₃, and H₂C₂O₄·2H₂O in a molar ratio of 1 : 1 : 2 : 2 at 150ºC for 7 days. The powder X-ray diffraction pattern of as-synthesized compound is in good agreement with the simulated one on the basis of single crystal data, indicating the phase purity of as-synthesized compound (Fig. S1, ESI†). The variation of the molar ratio of reactants often resulted in the formation of a layered cobalt phosphite oxalate (H₂O)₂·Co₃(HPO₃)₄ or a mixture of this inorganic solid and compound 1. CHN elemental analysis of compound 1 gave C 12.16 wt%, H 2.72 wt% and N 14.36 wt%, consistent with the calculated values of C 12.51 wt%, H 2.80 wt% and N 14.59 wt%. IR spectrum indicates the presence of phosphite units and oxalate ligands in the structure (Fig. S2, ESI†). The band at 2420 cm⁻¹ is due to the stretching vibration of P–H bonds, and the strong bands at 1610 and 1320 cm⁻¹, correspond to the C=O and C–O stretching vibrations of the oxalate groups.

Compound 1 crystallizes in the monoclinic space group P2₁/n (no. 14). There are one Co atom, one H₃PO₃ unit, two halfs of oxalate ligands, and one guanidinium cation in the asymmetric unit (Fig. S3, ESI†). The Co atom is octahedrally coordinated by six oxygen atoms from two oxalate ligands and two H₃PO₃ units. The H₂C₂O₄ unit makes two P–O–Co connections to adjacent metal centers. The linkages between H₃PO₃ units and CoO₆ octahedra generate inorganic helical chains running along the [010] direction, as shown in Fig. 1a. The pitch of the helix is 7.4104(2) Å, which is equal to the periodicity along the crystallographic b axis. Each oxalate ligand in the structure connects two Co atoms in a bisbidentate chelating coordination mode. As a result, zigzag cobalt oxalate chains are generated, which run along the [100] direction (Fig. 1b). The Co–O bond lengths in the range of 2.041(2)-2.119(2) Å, and the P–O bond lengths vary from 1.493(2) Å to 1.557(2) Å. The helical inorganic chains are linked by zigzag oxalate chains through common CoO₆ octahedra to result in a three-dimensional open-framework structure, as shown in Fig. 1c.
Viewed along the [100] direction, the structure exhibits 12-ring channels delimited by six CoO₆ octahedra, four H₂PO₃ pseudo pyramids, and four oxalate ligands. There are another type of 12-ring channels running along the [010] direction, which is delimited by six CoO₆ octahedra, two H₂PO₃ pseudo pyramids, and four oxalate ligands. The guanidinium cations are orderly within the intersecting channels and interact with the host framework through extensive hydrogen bonds. The closest N···O distances are between 2.716(3)-3.086(3) Å. These organic cations occupy 40.4% of the unit cell volume (calculated using the program PLATON). 13

By regarding Co atoms as the 4-connected nodes, the framework structure of 1 can be understood as a diamondoid network (Fig. 1d). Such framework topology is observed for the first time in phosphite-oxalate hybrid solids. Prior to this work, only one example of open-framework cobalt phosphite-oxalate is known: [Co₂(N₂H₅)₂(HPO₃)₂(C₂O₄)₃]. 14 This hybrid solid contains one-dimensional 8-ring channels with infinite Co−O−Co chains, which is different from the framework structure of compound 1.

Light-pink crystals of compound 2 were obtained by heating a mixture of Mn(OAc)₂·4H₂O, guanidinium carbonate, H₂PO₃, and H₂C₂O₄·2H₂O in a molar ratio of 1 : 1 : 1 : 1.2 at 150 °C for 10 days. The variation of the molar ratio of reactants often resulted in the formation of a mixture of a new manganese phosphite (H₂O)₂Mn₂(HPO₃)₃ and compound 2. The phase purity of as-synthesized compound 2 was confirmed by powder X-ray diffraction pattern (Fig. S4, ESI†) and elemental analysis (anal. C 13.94 wt%, H 2.83 wt% and N 14.07 wt%; calc. C 14.16 wt%, H 2.89 wt% and N 14.16 wt%). IR spectrum contains a strong band at about 2380 cm⁻¹, in good agreement with the existence of H₂PO₃ pseudo pyramids in the crystal structure (Fig. S5, ESI†). The stretching vibration of C=O and C−O bonds are observed at 1610 and 1320 cm⁻¹.

Compound 2 crystallizes in the triclinic space group P-1 (no. 2). The asymmetric unit contains 32 independent non-hydrogen atoms, of which Mn1 lies on an inversion center (Fig. S6, ESI†). Each Mn atom is octahedrally coordinated by oxygen atoms with the Mn−O bond lengths in the range of 2.095(2)-2.304(2) Å. The P atom makes three P−O−Mn connections to adjacent Mn atoms, with the fourth vertex occupied by a terminal hydrogen atom. The linkages between MnO₆ octahedra and HPO₃ pseudo pyramids create a chain-like substructure, as shown in Fig. 2a. The P−O bond lengths are between 1.516(2)-1.523(2) Å, and the P−H bond length is 1.369 Å.

There are two types of oxalate ligands in the structure. Type I oxalate ligands adopt a typical bisbidentate chelating coordination mode, as that found in compound 1. Type II oxalate ligands adopt a bisbidentate chelating/bridging coordination mode. The connectivity between MnO₆ octahedra and oxalate ligands results in the formation of a layered substructure, which featured large 16-ring windows and Mn₂O₁₁ dimers (Fig. 2b).

The manganese phosphite chains share common MnO₆ octahedra with manganese oxalate layers to produce a three-dimensional open-framework structure (Fig. 2c). Viewed along the [100] direction, the structure has 10-ring channels delimited by six MnO₆ octahedra, two HPO₃ pseudo pyramids, and two oxalate ligands. Intersecting these 10-ring channels are those large 12-ring channels running along the [010] and [001] directions, respectively. The guanidinium cations locate in the free voids and balance the overall negative electrostatic charge of the hybrid framework. A void space analysis using the program PLATON indicates that all extrframework cations occupy 39.6% of the unit cell volume.

It is of interest to compare the structure of compound 2 with other related inorganic-organic hybrid frameworks. So far, three open-framework manganese phosphite-oxalates were prepared in the presence of different dianimes as the structure-directing agents. 15 All of them have three-dimensional structures with manganese phosphates layers cross-linked by oxalate ligands. In comparison, the framework structure of compound 2 can be understood as manganese oxalate layers linked through HPO₃ units.

We have also investigated the use of other transition metal ions (i.e., Zn²⁺, Cd²⁺, and Ni²⁺) as the framework cations to prepare new open-framework structures. Preliminary results showed that the replacement of Co(OAc)₂·4H₂O by Zn(OAc)₂·2H₂O, but otherwise similar synthetic conditions as used for 1 gave rise to a new Zn-based compound isostructural to compound 1. In the case of other metal ions, only powder or microcrystalline products were obtained.

with unidentified structures were obtained.

Thermogravimetric analysis, carried out in a flow of air with a heating rate of 10 °C/min, showed that compound 1 remained stable up to 100 °C (Fig. S7, ESI†). The weight loss of 3.3% between 100-150 °C may be attributed to the dehydrated process involving H₃PO₃ units (observed: 3.3%; expected 3.2%). The organic cations and oxalate ligands started to decompose over 265 °C. For compound 2, the weight loss of 6.0% between 100-220 °C is due to the departure of crystalline water molecules (expected 6.1%). A plateau region in the temperature region 220–260 °C indicates that the framework structure is stable up to 260 °C. On further heating, the organic cations in the structure start to decompose (Fig. S8, ESI†).

The magnetic moment (μB) at 300 K per mole of metal atom is 5.09 μB for 1, which, while significantly larger than the spin-only value of 3.87 μB due to strong orbital contributions, is comparable to those reported for other Co(II) compounds.17 For compound 2, the magnetic moment at 300 K per mole of metal atom is 5.73 μB, in agreement with the expected spin-only value of Mn(II) in the high spin state (5.92 μB).18 The thermal evolution of χ'' follows the Curie-Weiss law at temperature above 20 K (for 1) and 13 K (for 2), with C_m = 4.46 cm³ K mol⁻¹ and θ = -95.0 K (for 1), and C_m = 4.61 cm³ K mol⁻¹ and θ = -26.3 K (for 2). The negative θ values indicate the existence of antiferromagnetic interactions between the metal centers.

In summary, two new metal phosphate-oxalates have been synthesized in a solvent-free flux of phosphorous acid and oxalic acid. The two compounds display different open frameworks with diamondoid and pillarated-layered structures, demonstrating that solvent-free approach is effective in the synthesis of high quality single crystals of open-framework structures. Given the large variety of structure-directing agents, various metal ions and oxo anions, and rich coordination modes of oxalate ligand, we believe that this synthetic approach will offer exciting opportunities to prepare new crystalline inorganic-organic hybrids with open frameworks and appealing properties.

This work was supported by the NSFC of China (no. 21171211), and the Program for New Century Excellent Talents in University (no. NCET-12-0375).
