This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
Unprecedented Silicon(II)→Calcium Complexes with N-Heterocyclic Silylenes

Burgert Blom, Günter Klatt, Daniel Gallego, Gengwen Tan and Matthias Driess

The first N-Heterocyclic Silylene (NHSi) complexes of any s-block element to date are reported for calcium: \([\eta^5\text{-C}_5\text{Me}_5\text{Ca←:Si(OqCPh)}\{\text{N}^1\text{Bu}\}_2\text{Ca}\} (6)\) and \([\eta^5\text{-C}_5\text{Me}_5\text{Ca←:Si(N}^1\text{Bu\text{CH})}_2\text{Ca}\} (7)\). Complexes 6 and 7 are isolable in a facile way upon reactions of the corresponding free N-Heterocyclic Silylenes (NHSis) with \([\eta^5\text{-C}_5\text{Me}_5\text{Ca}\} (2)\). Complexes 6 and 7 were fully characterised by spectroscopic means and single crystal X-ray diffraction analysis of 6 is also reported. Analysis of the bonding situation by DFT methods including a Bader Atoms in molecules (AIM) analysis is also reported. The bonding interaction between the Si and Ca centres in 6 and 7 can best be viewed as \(\sigma\)-donor-acceptor interactions, with a considerable ionic contribution in the bond. The reactivity towards the oxygen containing substrates: THF and benzophenone is also discussed.

Introduction

N-Heterocyclic Silylene (NHSi) complexes have been reported across the transition metals, and a plethora of studies have been carried out to date, even highlighting their potential applications in catalysis. These efforts have been heralded by the high abundance, low toxicity and cost of silicon. Remarkably, no reports of NHSi complexes for any f-block elements exist, particularly for the alkaline earth metals, although two seminal reports for f-block NHSi complexes have been reported. This is somewhat surprising since employing environmentally benign alkaline earth metals, such as calcium, might enable access to inexpensive and environmentally friendly NHSi complexes for catalysis, stoichiometric transformations, or as precursors for silicate glasses. Herein we report the first group 2 (alkaline earth metal) calcium NHSi complexes readily accessible in a quantitative fashion by simple coordination reactions with the corresponding NHSis. Preliminary reactivity studies are also reported in addition to the theoretical calculations by DFT methods elucidating the bonding situation between the Ca and Si centres.

Results and Discussion

The starting point in our study was to investigate the reaction of the chlorosilylene of Roessky: \(\text{Si(PhC(N}^1\text{Bu})_2\text{Cl})\) (1) with \([\eta^5\text{-C}_5\text{Me}_5\text{CaCl(thf)}_2\} (3)\) (Fig. 1) and \(\text{Si(Cp}^\#\text{)(PhC(N}^1\text{Bu})_2\text{Cl})\) (4), when dissolved in thf, by salt metathesis as opposed to the desired coordination compound \([\eta^5\text{-C}_5\text{Me}_5\text{Ca←:Si(PhC(N}^1\text{Bu})_2\text{CPh)}\}^\#\) (See ESI†).

In order to suppress this metathetical reaction, the NH-silylene 1 was functionalised with an aryloxy substituent affording the novel NHSi: \(\text{Si(O-C}_5\text{H}_2\text{Bu})_2\text{Cl})\} (5), since cleavage of the Si-O bond in the latter is highly unlikely, due to the exoergic nature of silicon. Indeed this strategy enables facile and quantitative entry to the first s-block silylene complex: \([\eta^5\text{-C}_5\text{Me}_5\text{Ca←:Si(O-C}_5\text{H}_2\text{Bu})_2\text{Cl})\} (6)\) as a colourless solid, upon reaction of 5 with 2 in toluene at room temperature (Scheme 1). Strikingly, preferential coordination to Ca occurs via the Si atom and not the O atom in compound 6. This is likely due to the high steric demand of the aryloxy substituent precluding O coordination.
Scheme 1 Synthetic entry to the first NHSi calcium complex by coordination of 5 to calcium precursor 2.

The same synthetic methodology can also be employed to prepare the three coordinate NHSi complex \([\eta^5-C_5Me_5]_2:\text{Ca}\rightarrow:Si(N^\text{Bu}CH)_2\] (7) by reaction of the West silylene \(Si(N^\text{Bu}CH)_2\) (8) with the calcium precursor 2 in an analogous way. This affords compound 7 nearly quantitatively as a colourless solid (Scheme 2).

Scheme 2 Synthetic entry to the three coordinate NHSi calcium complex 7.

Complexes 6 and 7 are remarkable examples of molecular compounds featuring Ca-Si bonds, which are exceptionally rare.\(^8\) The most diagnostic spectroscopic feature for compounds 6 and 7 is the \(^{29}\text{Si}\) NMR shift in solution (6: \(\delta = -13.7\) ppm; 7: \(\delta = 81\) ppm, both in \(\text{C}_6\text{D}_6\)). Strikingly, these chemical shifts are only marginally deshielded from the uncoordinated NHSi (\(\delta = -22.8\) and \(\delta = 78.3\) ppm\(^7\) respectively) in both cases. This observation is in contrast to d-block NHSi complexes where a dramatic deshielding effect is observed on coordination and suggests only a very weak interaction between the Si and Ca centres in both complexes.

Dissociation in solution can be ruled out since \(^{29}\text{Si}\) MAS-solid state NMR spectroscopy revealed an identical chemical shift as to the solution spectrum for compound 7. Crystals of compound 6 suitable for single crystal X-ray diffraction analysis were obtained from a concentrated toluene solution with slow cooling to -30 °C. In the case of compound 7 a similar procedure also consistently afforded crystals visually of high quality, but the quality of the diffraction data was of low quality (\(R_1 = 0.1855\) for \(I > 2\sigma(I)\)), despite several measurements and many other crystallisation procedures. Despite this, the structural motif was unambiguously located in the structure solution (see ESI\(^+\)), and the metrical parameters are in good agreement with the calculated structure (BP86-D3 functional plus DZP basis set). Fig. 2 depicts the solid state structure of compound 6 and the geometry optimised structure of 7.

Both compounds feature rather long Ca-Si bond lengths: in compound 7, bearing a three-coordinate Si atom, this distance is shorter by 18 pm compared to compound 6, indicating stronger coordination in the former compound. The observed difference in bond length might be due to steric as compound 6 bears a substantially more sterically congested NHSi than compound 7 which would impede coordination thereby resulting in an elongated bond length. The bond lengths are somewhat longer than those reported in the calcium silyl complex \(\text{Ca}(\text{thf})_2\text{Si(SiMe}_3)_2\) at 3.042(9) and 3.086(9) Å respectively.\(^8\) Moreover, in both compounds, this bond distance is significantly larger than the sum of the single bond covalent radii proposed by Pyykkö and Atsumi\(^7\) for Ca (1.71 Å) and Si (1.16 Å) = 2.87 Å which led us to question whether it is merely an electrostatic interaction, with no covalent character. In order to address this point we performed DFT calculations to elucidate the nature of the bonding interaction between Si and Ca in both compounds (BP86-D3 and the DZP basis).

In compound 6, the LUMO, \(E = -0.085\) eV, is located mostly on the phenyl residue while the HOMO, \(E = -0.146\) eV, mostly involves the \(\text{Cp}^*\) ligands with some involvement of the Ca centre (Fig. 3a). Similarly, in compound 7 the LUMO \(E = -0.063\) eV, is mostly Si(p) + 2 × N(p) + 2 × C(p) while the HOMO, \(E = -0.151\) eV, is also mostly located on the \(\text{Cp}^*\) ligands with some involvement of the Ca centre and (Fig. 3b).

Fig. 2 ORTEP representation of the molecular structure of compound 6 in the solid state (left). Thermal ellipsoids set at 50 % probability level and H atoms omitted for clarity. The geometry optimised structure of 7 (right) (BP86-D3 functional plus DZP basis set). For 6: \(d(\text{Ca-Si}) = 3.2732(5)\) Å. 7: \(d(\text{Ca-Si}) = 3.090\) Å (calcd.).
The most interesting MO in both compounds signifying the Si-Ca interaction is in both cases the HOMO-5 \( \sigma \): \( E = -0.207 \) eV; \( \sigma \): \( E = -0.230 \) eV, which clearly shows a donor-acceptor interaction between Si and Ca in both compounds (Fig. 4). Notably, in both cases some interaction arises from the Ca centre in the MO. Moreover, the calculated Wiberg-bond index (WBI) of compound \( \sigma \) = 0.47 while in compound \( \sigma \), in accord with the decreased Ca-Si bond length observed experimentally, is slightly higher at 0.53. These indices are indicative of a covalent bonding interaction between the Ca and Si centres in both compounds.

Fig. 4 Plot of the boundary surfaces of the HOMO-5 in \( \sigma \) (left) Occupancy is 1.91, with 86\% Si sp- and 14\% Ca spd-contribution. In \( \sigma \) (right) occupancy is 1.95, with 85\% Si sp- and 15\% Ca spd-contribution.

In contrast, a Bader atoms in molecules (AIM) analysis of compound \( \sigma \) (See ESI† and Fig. 5) revealed a (3, -1) bond critical point (BCP) between the Ca and Si centres with \( \rho(r) = 0.0175 \) a.u and \( \nabla^2 \rho(r) = 0.0657 \) a.u. at the bond critical points (BCP). These values indicate a closed-shell (ionic) interaction between the two centres. Moreover the ratio of the eigenvalues \( \lambda_1|\lambda_3 = 0.127 \) (\( \lambda_1 = -0.0115 \), \( \lambda_2 = -0.0130 \), \( \lambda_3 = 0.0902 \)) is also indicative of a close-shell interaction. Hence the AIM analysis points to a substantial ionic character in the Si-Ca interaction; at odds with the positive WBI clearly indicating covalency in the bond. These results collectively show that the Ca-Si bonding interaction is perhaps therefore best described as a \( \sigma \)-donor acceptor interaction between Si and Ca which bears considerable ionic character.

Fig. 5 Contour map of the Laplacian in compound \( \sigma \). Negative values are indicated by a dotted line (where there is charge concentration), and solid lines where the Laplacian is positive (charge depletion).

The labile coordination of the NHSi in compound \( \sigma \) was shown by the reaction with THF where immediate NHSi elimination results with concomitant formation of \( [[\eta^5-C_5Me_5]_2Ca(thf)]_2 \) (2•2thf), observed in the \( ^1H \) NMR spectra. This result is certainly due to the highly oxophilic nature of the Ca centre. We next attempted a cycloaddition reaction of benzophenone with \( \sigma \) with the goal of forming the cycloaddition product \( \eta \) (see Scheme 3). Even in this instance, the NHSi 8 is eliminated with concomitant formation of a dark purple ketone adduct \( [[\eta^5-C_5Me_5]_2Ca\rightarrow:O=CPh]_2 \) (10) (Fig. 6). The isolation and formation of 10 in this reaction dramatically highlights the weak coordination of the NHSi to Ca, which is even eliminated by a ketone coordination. Again, the oxophilic nature of the Ca centre likely drives this process.

Scheme 3 Reaction of compound \( \sigma \) with benzophenone does not afford the expected cycloaddition product \( \eta \), rather the formation of the ketone adduct 10 with concomitant elimination of NHSi 8 is observed.

Fig. 6 ORTEP representation of the molecular structure of ketone adduct 10 in the solid state. Thermal ellipsoids set at the 50 \% probability level, H atoms omitted for clarity. Selected bond lengths (Å): Ca1-O1 2.293(2), O1-C33 1.238(3).

Conclusion

The first examples of \( \sigma \)-block N-Heterocyclic Silylene complexes (NHSi) have been reported for the group 2 alkaline-earth metal element calcium. These complexes are also the only existing examples of any \( \sigma \)-block NHSi coordination compound to date. The four or three coordinate NHSi complexes can be prepared in a quantitative fashion upon reaction of the free NHSiS with the readily available precursor \( [[\eta^5-C_5Me_5]Ca\rightarrow:Si(O-C_6H_4-2-Bu)](N' Bu)_2CPh] \) (6) and \( [[\eta^5-C_5Me_5]Ca\rightarrow:Si(N' BuCH)_2] \) (7) respectively. Both compounds exhibit remarkably long Ca-Si bond lengths, but on the basis of DFT investigations these can be considered simple donor-acceptor interactions from Si to Ca, with considerable
ionic character. The NHSi in compound 7 is very labile to substitution, and is readily eliminated by THF and even benzophenone, affording in the latter case the ketone adduct: [(η⁴-C₅Me₅)₂Ca=O-CPh₂] (10). This showcases the rather low bond energy of the Ca-Si bond. We are currently exploring NHSis that bind more strongly to the Ca centre which might enable novel Ca,Si mediated processes, without NHSi elimination. We are also currently extending this synthetic approach to other group 2 elements (Ba and Sr) and will report these findings in due course.

Experimental Section

All experiments were carried out under dry oxygen-free nitrogen using standard Schlenk techniques. Solvents were dried by standard methods and freshly distilled and degassed prior to use. The NMR spectra were recorded on Bruker spectrometers (AV400 or AV200) referenced to residual solvent signals as internal standards (1H NMR: C₆D₆, 7.15; THF-d₈, 3.58 (left signal) ppm and 13C (1H): NMR: C₆D₆, 128.0; THF-d₈, 67.6 (left signal) ppm) or with an external standard (SiMe₄ for ²⁵Si NMR). Concentrated solutions of samples were sealed off in a Young-type NMR tube for measurements. Signals were unambiguously assigned by a combination of H,H COSY, HSQC and HMBC correlation 2D experiments. Melting points were recorded on a “Melting point tester” device from BSGT company and are uncorrected. All the samples are sealed off in capillary under vacuum and each sample was measured in duplicate. High resolution ESI mass spectra were recorded on an Orbitrap LTQ XL of Thermo Scientific mass spectrometer and the raw data evaluated using the Xcalibur computer program. For the single crystal X-ray structure analyses the crystals were each mounted on a glass capillary in perfluorinated oil and measured in a cold N₂ flow. The data were collected on an Agilent Technologies SuperNova (single source) at 150 K (CuKα radiation, λ= 1.5418 Å) and refined on FC with the SHELXL-97 software package. The positions of the H atoms were calculated and considered isotropically according to a riding model. Solid state ²⁵Si (¹H) static and MAS cross polarization (CP) measurements were carried out on a Bruker Avance II spectrometer at an external magnetic field of 9.4 T (i.e. a ²⁵Si resonance frequency of 79.46 MHz) using a standard Bruker 4 mm double-resonance H-X MAS probe. The CP spectra were recorded with a cross polarization time of 2 ms and composite pulse ¹H decoupling was applied during the acquisition. The spectra were referenced externally to TMS (tetramethylsilane) using TKS (tetrakis(trimethylsilyl)silane) as a secondary reference. Benzophenone was purchased from Aldrich and used as received. [(η⁴-C₅Me₅)₂Ca] (2) was prepared from Ca(N(SiMe₃)₂)₂ upon reaction with Cp³H and purified by sublimation as a white crystalline solid as previously reported by Tanner et al.¹³ The NHSiI was prepared via literature procedures. Synthesis of N,N-di-tet-butyl phenylamidinate(2-tet-butyl-phenolate) silylene (5)

The synthesis was carried out following the reported procedure for the synthesis of N-donor stabilized silylenes Ph(C₅N₃Bu)₆SiX reported by Roesky et al.¹⁴ with slight modifications. 2-tet-butylphenol (0.558 g, 3.71 mmol) was dissolved in 20 mL of diethyl ether and Et₂BuLi 1.6 M (2.3 mL, 3.7 mmol) was added via syringe at -20 °C. After stirring for 2 h at room temperature, the reaction mixture was cooled down to -78 °C and a solution of PhC(N₃Bu)₂SiCl (1) (1.066 g, 3.61 mmol) in 20 mL of toluene was transferred via cannula. The reaction was slowly warmed up to room temperature overnight. Removal of volatiles in vacuo, hexane extraction and crystallization at -30°C afforded 0.914 g of the desired product in high purity (65% yield). ¹H NMR (400.13 MHz, CDCl₃, 298K, ppm): δ = 1.10 (s, 18H, 2 × NC(CH₃)₃), 1.67 (s, 9H, 1 × Ar-C(CH₂)), 6.86-7.00 (m, 5H, Ph), 7.20-7.24 (m, 2H, C₁⁻H and C₅⁻H) 7.41 (dd, 1H, 3J(H₁) = 7.9 Hz, 3J(H₁) = 1.8 Hz, C₄⁻H) 7.73 (dd, 1H, 3J(H₁) = 8.2 Hz, 3J(H₁) = 1.4 Hz, C₃⁻H). ³¹C (¹H) NMR (100.61 MHz, CDCl₃, 298K, ppm): δ = 30.4 (s, 1 × Ar-C(CH₃)), 31.6 (s, 2 × NC(CH₃)₃), 32.3 (s, 1 × Ar-C(CH₂)), 53.1 (s, 2 × NC(C₆H₄)), 119.4 (s, 1 × C₂⁻OAr), 120.4 (s, Ar-C, Ph), 126.9 (s, 1 × C₂⁻OAr), 127.1 (s, 1 × C₃⁻OAr), 127.9 (Ar-C crossed with solvent peaks, located by HMQC/BC), 129.7 (s, Ar-C, Ph), 129.8 (s, 1 × C₃⁻OAr), 133.8 139.3 (both s, Ar-C), 157.5 (s, 1 × O-C, OAr), 163.9 (s, 1 × NCN). ²⁵Si (¹H) NMR (79.49 MHz, CDCl₃, 298K, ppm): δ = -22.8.

Reaction of 2 with chlorosilylene 1

A Schlenk tube was charged with [(η⁴-C₅Me₅)₂Ca] (2) (0.200 g, 0.644 mmol) and PhC(N₃Bu)₂SiCl (1) (0.189 g, 0.644 mmol). Freshly distilled toluene (40 mL) was condensed onto this solid mixture in a liquid nitrogen trap under static vacuum. The reaction mixture was slowly allowed to warm to room temperature with stirring. On warming to room temperature a bright yellow suspension is formed. The reaction mixture was allowed to stir at room temperature for 2 h. ¹H NMR of the reaction solution at this point revealed no benzene soluble products. The toluene supernatant solution was separated from the yellow solid by cannula filtration, and discarded. The remaining bright yellow solid was dried in vacuo for 2 h affording 0.356 g of the product. This solid is insoluble in tol-d₈, CDCl₃, and affords decomposed products in acetonitrile-d₃ and CD₂Cl₂. It dissolves completely in thf-d₈ and is shown to be a mixture of the dimer [(η⁴-C₅Me₅)₂CaCl(thf-d₈)]₂ (3) and [Si(Cp³)³Ph(C₅N₃Bu)] (4) on the basis of ¹H NMR, ³¹C NMR, ²⁵Si NMR and X-ray diffraction analysis. Attempts at separating the two components by fractional crystallisation methods failed, however some crystals, suitable for XRD of [(η⁴-C₅Me₅)₂CaCl(thf)] were obtained fortuitously upon dissolving a sample of the yellow solid obtained from this reaction in THF (non-deuterated) and cooling to -30 °C. ¹H NMR (200 MHz, THF-d₈, 298 K, ppm): δ = 1.00 (s, 9H, 2 × NC(CH₃)₃), 1.73 (s, 13H, 1 × C₆H₄(2,6-Me₂)), 0.5 [(η⁴-C₅Me₅)₂CaCl(thf-d₈)]₂, 1.87 (s, 6H, 2 × η⁵-C₅PH₃), 1.92 (s, 6H, 2 × η⁵-C₅PH₃), 1.99 (s, 3H, 1 × η⁵-C₅PH₃), 7.05 – 7.72 (m, 5H, Ar-H). No signals detected for coordinated thf in [(η⁴-C₅Me₅)₂CaCl(thf-d₈)] due to deuterium. ³¹C (¹H) NMR (50 MHz, THF-d₈, 298 K, ppm): δ = 11.9 (s, η⁵-C₅(CH₃)), 13.6 (s, η⁵-C₅(CH₃)), 32.3 (s, NC(CH₃)₃), 53.9 (s, NC(CH₃)₃), 111.9 (s, η⁵-C₅(CH₃)), 122.3 (s, 2 × η⁵-C₅(CH₃)), 130.4, 130.7, 131.9, 135.3 (all s, Ar-C), 160.8 (s, N-CN, Si(Cp³)³Ph(C₅N₃Bu)). (on the time scale of the ³¹C measurement, the Cp coordinated to Si is fluxional and in the η⁵ coordination mode). ²⁵Si (¹H) NMR (79 MHz, THF-d₈, 298 K, ppm): δ = 52.4 ppm (s, Si(Cp³)³Ph(C₅N₃Bu)).

Synthesis of [(η⁴-C₅Me₅)₂Ca=Si(O-C₅H₄-2-Bu)](N₅Bu₃)Phe(6)

A Schlenk tube was charged with [(η⁴-C₅Me₅)₂Ca] (2) (0.250 g, 0.805 mmol) and Si(O-C₅H₄-2-Bu)N₅Bu₃ (5) (0.328 g, 0.805 mmol) in the glove-box. Toluene (40 mL) was condensed onto this solid mixture in a liquid nitrogen trap under static vacuum.
The reaction mixture was allowed to come to room temperature with rapid stirring. Upon warming to room temperature a pale–yellow solution is observed. After 1 h of stirring at room temperature a $^1$H NMR spectrum showed completion of the reaction. The reaction solution was concentrated to ca. 3 mL and cooled to $-30^\circ$C for 1 h. A colourless precipitate was isolated by removal of the supernatant liquid via syringe and dried in vacuo for 1 h ($5 \times 10^{-2}$ mbar). Yield: 0.570 g; 99%, m.p. 134 °C (turns to a pale yellow oil). $^{13}$C NMR (400 MHz, CD$_2$Cl$_2$, 298 K, ppm): $\delta = 6.83$ (2H, 1 × CH=CH$_2$), 7.02 (m, 5H, 1 × {(N$_2$C$_{6}$H$_5$)$_2$C=O}), 7.18 – 7.24 (m, 2H, 1 × C=O-CH$_2$), 7.36 (d, 2H, $^3$J(H,H) = 7.8 Hz, 1 × C=O-CH$_2$, OAr), 7.40 (d, 1H, $^3$J(H,H) = 7.8 Hz, 1 × C=O-H, OAr). 

The remaining colourless residue was required dissolved in CD$_2$Cl$_2$ and cooled to $-30^\circ$C for 18 h. 

Synthesis of [(η$^5$-C$_5$Me$_5$)$_2$Ca–=Si(NBu’’Cl)$_2$] (7) 

A Schlenk tube was charged with $[\{\eta^5$-C$_5$Me$_5$]Ca$] (2) (0.310 g, 1.00 mmol) and Si(NBu’’Cl) (8) (0.196 g, 1.00 mmol). Freshly distilled tolulene (15 mL) was condensed onto this solid mixture in a liquid nitrogen trap under static vacuum. The reaction mixture was allowed to come to room temperature upon which a colourless solution had formed. The reaction was stirred at room temperature for 40 minutes and the solvent removed in vacuo, affording a colourless solid as product, which is spectroscopically pure and requires no further purification. Crystals suitable for X-ray diffraction analysis were grown from toluene, although despite several measurements the data set is only of average quality. Yield: 0.507 g (100%). $^1$H NMR (400 MHz, CD$_2$Cl$_2$, 298 K, ppm): $\delta = 1.32$ (s, 18H, 2 × NC(CH$_2$)$_2$), 2.12 (s, 30H, 2 × C$_3$(CH$_3$)$_3$), 6.58 (s, 2H, 1 × CH=CH$_2$), 11.31 (s, 1 × C=O), 12.21 (s, 2 × C$_3$(CH$_3$)$_3$), 124.0 (s, 2 × C$_3$(CH$_3$)$_3$), 129.0 (s, 2 × $^2$Bu), 130.6 (s, 2 × C$_3$(CH$_3$)$_3$), 133.5 (s, 1 × C$_3$(CH$_3$)$_3$) ppm. 

The identity of 7 was confirmed by the synthesis of 10 directly from the reaction of $[\{\eta^5$-C$_5$Me$_5$]Ca$] (2) with Benzenophenone as follows: A 

Schlenk tube was charged with $[\{\eta^5$-C$_5$Me$_5$]Ca$] (2) (0.412 g, 1.326 mmol) and benzophenone (0.240 g, 1.326 mmol). The two solids were mixed by stirring at room temperature and a colour change (in the solid state) was immediately observed to bright purple. Toluene (10 mL) was added to the purple solution and the formed purple solution stirred at room temperature for 1 h. The solvent was removed in vacuo affording the product as a purple solid. Yield: 0.650 g, 100%). $^1$H NMR (400 MHz, CD$_2$Cl$_2$, 298 K, ppm): $\delta = 2.07$ (s, 3OH, 1 × $^2$C$_2$(CH$_2$)$_2$), 7.00 (s, 4H, $^3$J(H,H) = 7.8 Hz, 2 × C$_3$(CH$_3$)$_3$, Ph), 7.11 (d, 2H, $^3$J(H,H) = 7.8 Hz, 2 × C$_3$(CH$_3$)$_3$, Ph), 7.46 (d, 4H, $^3$J(H,H) = 7.8 Hz, 2 × C$_3$(CH$_3$)$_3$, Ph), 120.6 (s, 2 × $^2$Bu), 130.6 (s, 2 × C$_3$(CH$_3$)$_3$), 133.5 (s, 2 × $^2$Bu) ppm.

The synthesis of ketone adduct 10 can also be achieved by the reaction of benzophenone with 2, affording 10 quantitatively. This reaction can remarkably even be carried out in the solid state without any solvent.

Abstract

The first N-Heterocyclic Silylene (NHSi) complexes of any s-block element to date are reported for calcium: 
\[[\eta^5-C_3Me_3]_2Ca\leftarrow:Si(O-C_6H_4-2'-Bu)\{(N^3Bu)_3CPh\}] \text{ and } \[(\eta^5-C_3Me_3)\_2Ca\leftarrow:Si(N^3BuCH)\_2] \]. The synthesis, structure, bonding analysis by DFT methods and the reactivity towards oxygen containing substrates is discussed.
