**Abstract**

Mulberry extract (ME) has been shown to possess beneficial effects towards obesity, but its mechanism is still unclear. In small mammals, mitochondria enriched brown adipose tissue (BAT) is known to convert proton electrochemical energy to heat and maintain a constant body temperature. Improving mitochondrial function or increasing the number of mitochondria could promote the metabolism of carbohydrate and fat. Thus, this study was designed to investigate the mitochondria function regulated by ME and mulberry wine extract (MWE) during the brown adipogenesis. The C<sub>3</sub>H<sub>10</sub>T<sub>1/2</sub> mesenchymal stem cell was treated with ME and MWE, which both significantly ( $p < 0.05$ ) increased the expression levels of fatty acid oxidation related genes such as peroxisome proliferator-activated receptor- $\gamma$  coactivator-1 $\alpha$ , PR domain-containing 16 and carnitine palmitoyltransferase 1 $\alpha$  during brown adipogenesis. These changes were accompanied with increases in mitochondrial oxidative complex proteins upon ME and/or MWE exposure. Notably, ME and/or MWE also significantly ( $p < 0.05$ ) increased the expression of transcription factor A and nuclear respiratory factor-1, which are the key transcription factors of mitochondrial biogenesis. In parallel, mitochondrial copy number and brown adipose tissue specific gene—uncoupling protein-1 expression were dramatically ( $p < 0.05$ ) elevated after ME or MWE treatment. Cyanidin-3-glucoside (Cy-3-glu), which was found to be one of the most abundant anthocyanins in ME and MWE. Therefore, the BAT regulatory activity of ME and MWE might be, at least in part, due to the effect of Cy-3-glu. These results suggested that ME and MWE could ameliorate metabolic disease through an improvement in mitochondrial functions.

44

## 47 **Introduction**

48 Mulberry is the fruit of *Morus alba* L. and is a traditional Chinese edible fruit that shows  
49 beneficial pharmacological effects including anti-inflammation<sup>1-2</sup>, anti-oxidative stress<sup>3</sup>,  
50 improvement of cardiac function<sup>4</sup>, prevention of Alzheimer's disease<sup>5</sup>, and anti-obesity<sup>6</sup>. Mulberry  
51 extracts contain high amounts of water-soluble anthocyanins, which are the most important  
52 antioxidative compounds in the plant kingdom<sup>7</sup>. Multiple lines of evidence suggest that  
53 anthocyanins have biological and pharmacological benefits including anti-bacterial,  
54 anti-inflammatory, anti-oxidative, and immune system-stimulating properties<sup>8</sup>. In addition,  
55 resveratrol—another component of mulberry fruits—inhibits adipogenesis *in vitro*<sup>9</sup> and improves  
56 pathophysiological conditions such as dyslipidemia, hyper-insulinemia and hypertension<sup>10</sup>.  
57 Similarly with grape wine, mulberry wine which we used is also made from 100% fresh mulberry  
58 fruit juice by yeast fermentation. In addition to containing many nutrients, such as amino  
59 acids, vitamins and minerals, mulberry wine also enriches a variety of bioactive  
60 substances, including organic acid, polyphenols, especially, anthocyanins and resveratrol<sup>34</sup>.  
61 However, to the best of our knowledge, the function of mulberry wine has been rarely studied.  
62 Obesity is a major risk factor for metabolic disorders including type 2 diabetes, hypertension,  
63 cardiovascular disease, and other related diseases<sup>11</sup>. In mammals, white adipose tissue (WAT) stores  
64 energy, whereas brown adipose tissue (BAT) burns energy. As a thermogenic organ, BAT maintains  
65 body temperature during cold acclimation. BAT has a large number of mitochondria and uniquely  
66 expresses the BAT-specific gene uncoupling protein-1 (UCP1) that uncouples chemical energy to  
67 produce heat and maintain body temperature<sup>12-14</sup>. BAT has received great attention in treating  
68 obesity and related diseases because of its important roles in energy metabolism and systemic  
69 triglyceride clearance.

70 The anti-obesity and anti-diabetic effects of mulberry extract are well known<sup>4,15-16</sup>, but the  
71 molecular mechanism is not well studied<sup>2,15</sup>. A previous study suggested that mulberry fruit extract  
72 involves mitochondrial membrane potential and might work through a ROS-dependent  
73 mitochondrial pathway to regulate human glioma tumor cell growth<sup>17</sup>. Therefore, we hypothesized  
74 that mulberry fruit extract (ME) and mulberry fruit wine extract (MWE) might directly regulate the  
75 activity of BAT and mitochondrial function during brown adipogenesis. Finally, most of the  
76 research on BAT has been conducted on the C<sub>3</sub>H<sub>10</sub>T<sub>1/2</sub> mesenchymal stem cell, which is considered  
77 a suitable model for studying the function and pathophysiology of BAT. Thus, to explore this  
78 hypothesis, our study investigated the effects of ME and MWE on thermogenic genes and  
79 mitochondrial marker genes expressions using quantitative real time PCR in C<sub>3</sub>H<sub>10</sub>T<sub>1/2</sub> cells during  
80 brown adipogenesis. In addition, this article also measured the mitochondrial copy number by  
81 RT-PCR and quantified the mitochondrial specific oxphos protein using Western blotting after  
82 C<sub>3</sub>H<sub>10</sub>T<sub>1/2</sub> cells treated with ME and MWE. To the best of our knowledge, this is the first study of  
83 the effects of ME and MWE in brown adipogenesis.

84

## 85 **Materials and Methods**

### 86 **Chemicals and reagents**

87 An Amberlite XAD-7(Sigma, Sydney, Australia) and analytical reagent-grade solvents were used  
88 for the extraction of ME and MWE. 3-(4, 5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium  
89 bromide (MTT) and N, N-bis (salicylidene)-o-phenylenediamine vanadium (IV) oxide were  
90 obtained from Sigma Chemical Co. (St. Louis, MO, USA). Dulbecco's modified Eagle's medium  
91 (DMEM), fetal bovine serum (FBS) and streptomycin, penicillin were purchased from Gibco  
92 (BRL, Inchinnan, UK). Cyanidin-3-glucoside (Cy-3-glu, >99.0%), cyanidin-3-rutinoside

93 (Cy-3-rut, >99.0%), oligomycin, Carbonyl cyanide 4- (trifluoromethoxy) phenylhydrazine  
94 (FCCP), rotenone, anti-GAPDH and anti-beta actin were obtained from Sigma-Aldrich (St. Louis,  
95 MO, USA). HPLC grade acetonitrile and trifluoroacetic acid (TFA) were purchased from Merck  
96 (Germany).

97

### 98 **Plant materials and preparation of extracts**

99 Mulberry (*M. alba* L.) fruit (100 g) was macerated and stirred with 95% ethanol (500 mL). The  
100 extract was then purified through an Amberlite XAD-7 column. The polyphenolics were eluted with  
101 ~600 mL absolute ethanol with 1% (v/v) formic acid. The eluent was concentrated under reduced  
102 pressure at 35 °C and freeze-dried. The MWE was obtained from mulberry wine, which was  
103 produced by Wine Technology Development Center, China Agricultural University. Mulberry wine  
104 was concentrated under reduced pressure at 35 °C and lyophilised. ME and MWE were stored at  
105 -20 °C before use.

106

### 107 **Analysis of nutrient compositions of ME and MWE**

108 The total polyphenol content in ME and MWE was determined with a modified Folin-Ciocalteu  
109 method<sup>18</sup>. The results are presented in mg gallic acid equivalent (GAE)/100 g of sample on a dry  
110 weight basis (DW). The total anthocyanin contents of ME and MWE were directly determined  
111 using a pH differential method described previously<sup>19</sup>. The results were expressed as weight  
112 percentages, which were calculated as follows: (Cy-3-glu equivalent/wet weight of extracts or  
113 fractions) × 100. The contents of Cy-3-glu and Cy-3-rut in ME and MWE were measured with  
114 reverse phase HPLC (Waters, Milford, MA, USA) equipped with a photo diode array detector (PDA  
115 2996). Chromatographic separations were performed on a Merck LiChrospher 100RP-18e (Merck,

116 Germany) column (250 × 4.0 mm ID, 5 μm), protected by a Merck RP-18 (10 mm × 4.0 mm) guard  
117 column. The injection volume was 10 μL with a 0.4 mL/min flow. The mobile phases consisted of 2  
118 phases (A) and (B). Mobile phase (A) was 0.1% (v/v) TFA in water and mobile phase (B) was 0.1%  
119 TFA in water/acetonitrile (1/3, v/v). ME and MWE was dissolved in mobile phase (A) and filtered  
120 through a 0.22 μm membrane filter. The elution conditions were as follows: isocratic elution 10%  
121 (B), 0 to 10 min; linear gradient from 10% (B) to 60% (B), 50 min; to 90% (B), 55 min; at 10% (B),  
122 55 to 60 min. The column temperature was 40 °C and the detection wavelength was 520 nm.

123

#### 124 **Cell culture and brown adipogenesis**

125 C<sub>3</sub>H<sub>10</sub>T<sub>1/2</sub> cells, mouse mesenchymal stem cell line, were purchased from National Platform of  
126 Experimental Cell Resources (Sci-Tech, Shanghai, China). The cells were treated with brown  
127 adipogenic induction cocktails (DMEM containing 10% FBS, 1 μg/mL insulin, 1 μM  
128 dexamethasone, 0.5 mM isobutylmethylxanthine, 0.12 mM indomethacin, and 1 nM  
129 3,3',5-Triiodo-L-thyronine (T<sub>3</sub>) )for the first two days. The medium was then replaced by medium  
130 supplemented with only insulin and T<sub>3</sub>, which was changed every other day. The cells were  
131 treated with or without ME or MWE (10 μg/mL) for 6 days during brown adipogenesis. At day 6,  
132 the fully differentiated adipocytes were used for all experiments in this study.

133

#### 134 **Cell cytotoxicity assay**

135 Cell viability was measured using the MTT assay according to a protocol described previously<sup>20</sup>.  
136 Briefly, the cells were treated with ME and MWE at various concentrations (0, 12.5, 25, 50, 100,  
137 200, 400, 600, 800, and 1000 μg/mL) for 48 h; vehicle-treated cells served as a control. The 100 μL  
138 aliquots (0.5 mg/mL) of MTT were then added to each well. At the end of the experiment, the plates

139 were washed with phosphate buffered saline (PBS) buffer and lysed by adding 100  $\mu$ L of 10%  
140 sodium dodecyl sulfate (SDS) in 0.1 M HCl. The absorbance was measured at 550 nm (650 nm as  
141 the reference wavelength) on a plate reader (Synergy Hybrid Reader H1, Gene Group Company).  
142 Cell survival rate (%) was calculated as follows: [(mean absorbance of the sample - reference  
143 absorbance)/mean absorbance of the control]  $\times$  100.

144

#### 145 **RNA Isolation and Real-Time PCR**

146 Total RNA was extracted by using a Trizol reagent (Invitrogen). Reverse transcription of 2  $\mu$ g  
147 total RNA was performed with the high-capacity cDNA reverse transcription kit (Promega  
148 Biotech Co., Ltd.). Real-time PCR in triplicate was performed with a SYBR Green Master Mix  
149 (Promega Biotech Co., Ltd.). The PCR reactions were run in triplicate for each sample and  
150 quantified using the ABI Prism VIIA7 real-time PCR (Applied Biosystems). See Supplementary  
151 Table 1 for the details of primer sequences.

152

#### 153 **Western Blotting**

154 An equal amount of proteins from cell lysates were loaded in each well of a 12% SDS-PAGE gel  
155 after denaturation with SDS loading buffer. After electrophoresis, proteins were transferred to  
156 polyvinylidene difluoride membranes. The membranes were then incubated with blocking buffer  
157 (5% fat-free milk) for 1 h at room temperature, and then blotted with the following antibodies  
158 overnight: anti-UCP1, anti-OXPHOS (Abcam plc), anti-ERK1/2, anti-phospho ERK1/2,  
159 anti-AKT, anti-phospho AKT, anti-AMPK, anti-phospho AMPK, anti-p38 MAPK, anti-phospho  
160 p38 MAPK antibodies (Cell Signaling Technology, Inc.), anti-GAPDH and anti-beta actin. The  
161 membranes were incubated with HRP-conjugated secondary antibodies for 1 h at room

162 temperature. All signals were visualized and analyzed by densitometric scanning (Image Quant  
163 TL7.0, GE healthcare Bio-Sciences AB). Intensity values of the bands were quantified using  
164 Image J software (National Institutes of Health, USA).

165

#### 166 **Measurement of mitochondrial copy number**

167 Total DNA Isolation-Total DNA (genomic and mtDNA) was isolated from C<sub>3</sub>H<sub>10</sub>T<sub>1/2</sub> cells using  
168 the QIAamp DNA Mini kit (Qiagen) according to the manufacturer's instructions. DNA  
169 concentration was assessed using a Nanodrop 2000 (Thermo Scientific, Wilmington, DE, USA).  
170 The mtDNA copy number relative to the genomic DNA content was quantitatively analyzed with  
171 an ABI Prism VIIA7 real-time PCR (Applied Biosystems). The primers for COX-II and  $\beta$ -globin  
172 were as following:

173 COX-II: forward GCCGACTAAATCAAGCAACA, reverse CAATGGGCATAAAGCTATGG,

174  $\beta$ -globin: forward GAAGCGATTCTAGGGAGCAG, reverse GGAGCAGCGATTCTGAGTAG.

175

#### 176 **Measurements of oxygen consumption assay**

177 Mouse Primary Immortalized Brown Adipocytes- BAT-cMyc cells were seeded in gelatin-coated  
178 XF24 culture microplates (Seahorse Bioscience), and cultured in DMEM with 20% FBS and  
179 antibiotics (100 units/mL of penicillin and 100  $\mu$ g/mL of streptomycin) overnight at 37 °C with an  
180 atmosphere of 5% CO<sub>2</sub>. The next day, the cells were treated with the Cy-3-glu (10  $\mu$ M); DMSO  
181 served as the control. After 24 h, The O<sub>2</sub> consumption was measured with a Seahorse Bioscience  
182 XF24-3 extracellular flux analyzer. Basal respiration was also assessed in untreated cells. The cells  
183 were then treated with 10  $\mu$ mol/L oligomycin to measure the ATP turnover. The maximum  
184 respiratory capacity was assessed by 1  $\mu$ mol/L FCCP stimulation. Finally, mitochondrial respiration

185 was blocked with 1  $\mu\text{mol/L}$  rotenone and the residual oxygen consumption rate (OCR) was  
186 considered non-mitochondrial respiration.

187

## 188 **Statistical analysis**

189 All experiments were performed at least three times, and data are expressed as means  $\pm$  standard  
190 deviation (SD). Statistical significance was tested using a t-test. Statistical significance was set at  
191  $p < 0.05$ .

192

## 193 **Results**

### 194 **Analysis of nutrient contents of ME and MWE**

195 The total phenols and total anthocyanin contents of ME and MWE are shown in **Table 1**.  
196 Polyphenols were the main component of the two extract samples. The total amounts of phenolic  
197 compounds in ME and MWE were  $696.5 \pm 33.9$  GAE mg/g dry weight and  $876.2 \pm 36.1$  GAE  
198 mg/g dry weight, respectively. The total anthocyanin contents in ME and MWE were  $106.58 \pm$   
199  $3.34$  Cy-3-glu mg/g and  $65.69 \pm 2.78$  Cy-3-glu mg/g. Representative HPLC chromatographs of  
200 ME and MWE were shown in **Figure 1 A and B**. The two peaks at 520 nm were identified and  
201 quantified in relation to the authentic standard curves. ME and MWE contained Cy-3-glu ( $69.93$   
202  $\pm 1.31$  mg/g of dry weight and  $8.50 \pm 0.12$  mg/g of dry weight, respectively). The Cy-3-rut  
203 was  $32.05 \pm 0.69$  mg/g of dry weight and  $50.22 \pm 0.63$  mg/g of dry weight, respectively. The  
204 peaks were labeled (1) and (2) which correspond to Cy-3-glu and Cy-3-rut. The total anthocyanin  
205 and Cy-3-glu components in ME were higher than in MWE. There were more total phenolics in  
206 MWE than ME indicating that the high contents of the polyphenols resulted from  
207 yeast fermentation.

208

**209 Effects of ME and MWE on C<sub>3</sub>H<sub>10</sub>T<sub>1/2</sub> cell viability and brown adipogenesis**

210 The effect of ME and MWE on C<sub>3</sub>H<sub>10</sub>T<sub>1/2</sub> cell viability is shown in **Figure 2A**. The LC<sub>50</sub> of ME  
211 and MWE were calculated from a plot of dose dependent viability (%) (data not shown) with a  
212 linear relationship of  $y = -89.618x + 298.31$  ( $r^2 = 0.9718$ ) and  $y = -76.741x + 253.36$  ( $r^2 = 0.9946$ ),  
213 respectively. The LC<sub>50</sub> values of C<sub>3</sub>H<sub>10</sub>T<sub>1/2</sub> cells were  $589.9 \pm 46.7$   $\mu\text{g}/\text{mL}$  for ME, and  $446.6 \pm$   
214  $39.1$   $\mu\text{g}/\text{mL}$  for MWE. The growth of C<sub>3</sub>H<sub>10</sub>T<sub>1/2</sub> cells was inhibited in a dose-dependent manner  
215 (**Figure 2A**).

216 To investigate whether MWE or ME have an effect on brown adipogenesis, C<sub>3</sub>H<sub>10</sub>T<sub>1/2</sub> cells were  
217 treated with a brown adipogenic induction cocktail. The ME or MWE did not show significant  
218 effect during the formation of mature adipocytes (**Figure 2B**). In parallel, the gene expression  
219 levels of AP2, C/EBP $\alpha$ , C/EBP $\beta$ , and PPAR $\gamma$ 2 (adipogenic markers) were not altered in the MWE  
220 or ME treated groups. However, the level of C/EBP $\delta$  expression was significantly up-regulated ( $p$   
221  $< 0.05$ ) in the ME or MWE treated group (**Figure 2C**).

222

**223 ME and MWE enhanced the expression of thermogenic genes**

224 As adipogenesis was not affected by MW or MWE treatment, we interrogated whether there are  
225 any changes in BAT-specific gene expression. Interestingly, ME or MWE (10  $\mu\text{g}/\text{mL}$ )  
226 significantly increased ( $p < 0.05$ ) the expression levels of fatty acid oxidation related genes such  
227 as PGC1 $\alpha$ , PRDM16 and CPT1 $\alpha$  during brown adipogenesis (**Figure 2D**). Furthermore, the  
228 expression levels of UCP1 increased dramatically by 1.82- and 2.74-fold ( $p < 0.05$ ) in the ME and  
229 MWE treated groups, respectively (**Figure 2E**). These results indicated that ME and MWE  
230 treatment specifically regulated the thermogenic gene expressions in C<sub>3</sub>H<sub>10</sub>T<sub>1/2</sub> cells during brown

10

231 adipogenesis.

232

### 233 **ME and MWE increase mitochondrial copy number**

234 BAT burns energy, whereas WAT stores energy. As a thermogenic organ, one of the characteristic of  
235 BAT is a higher number of mitochondria, which reminded us that ME and MWE maybe can  
236 regulate mitochondrial function. We analyzed the expression of mitochondrial transcription factor A  
237 (Tfam) and nuclear respiratory factor-1 (NRF-1) using a quantitative real time PCR in C<sub>3</sub>H<sub>10</sub>T<sub>1/2</sub>  
238 cells (**Figure 3A** and **3B**).

239 In comparison to the control, the expressions of both Tfam and NRF1 increased more than 2-fold ( $p$   
240  $< 0.05$ ) after treatment with ME (**Figure 3A**) and MWE (**Figure 3B**). Tfam and NRF1 are  
241 well-known key players in mitochondrial biogenesis<sup>21</sup>. Therefore, we measured the mitochondrial  
242 copy number in C<sub>3</sub>H<sub>10</sub>T<sub>1/2</sub> cells, and the results showed that both ME and MWE significantly  
243 increased ( $p < 0.05$ ) the mitochondrial number in C<sub>3</sub>H<sub>10</sub>T<sub>1/2</sub> cells (**Figure 3C**).

244 To confirm this, the mitochondrial-specific oxphos protein was quantified with Western blotting.  
245 The levels of Ubiquinol-Cytochrome C Reductase Core Protein II (UQCRC2) and  
246 NADH Dehydrogenase (Ubiquinone) 1 Beta Subcomplex, 8 (NDUFB8) were significantly and  
247 consistently increased ( $p < 0.05$ ) in both ME and MWE treated groups (**Figure 3D**). However,  
248 UCP1, ATP5A, and Succinate Dehydrogenase Complex, Subunit B (SDHB) protein expression  
249 increased ( $p < 0.05$ ) only in the ME-treated group, but not in the MWE treated group (**Figure 3D**).  
250 These results indicated that ME and MWE significantly increased mitochondrial copy number  
251 during brown adipogenesis.

252

### 253 **ME increased p38 MAPK phosphorylation**

254 BAT is known to participate in blood glucose regulation and insulin sensitivity<sup>22</sup>. Our study has  
255 demonstrated that ME and MWE could dramatically increase the expression levels of UCP1, the  
256 key thermogenic gene, and other genes related to fatty acid oxidation. Therefore, we next tested  
257 whether ME or MWE influences insulin signaling pathways. Several proteins such as AMPK,  
258 AKT, ERK, and p-38, which were associated with the insulin signaling pathway, were analyzed  
259 by Western blotting (**Figure 3E**). Interestingly, the phosphorylation of p38 (P-p38) was  
260 significantly increased ( $p < 0.05$ ) after the ME treatment in C<sub>3</sub>H<sub>10</sub>T<sub>1/2</sub> cells during brown  
261 adipogenesis. These results indicate that ME, not MWE, regulates mitochondria function at least  
262 in part through the p38 pathway.

263

#### 264 **Cy-3-glu increased mitochondrial copy number and enhanced cellular oxygen consumption**

265 The ME and MWE contain large amounts of anthocyanin pigments such as Cy-3-glu and Cy-3-rut  
266 (**Table 1, Figure 1A and 1B**). We examined the effects of Cy-3-glu on the expression of  
267 thermogenic genes and mitochondrial copy number. Cy-3-glu significantly up-regulated the UCP1  
268 gene expression in a dose-dependent manner ( $p < 0.05$ ) (**Figure 4A**). Meanwhile, Cy-3-glu  
269 markedly increased BAT-selective thermogenic genes including PRDM16, PGC1 $\alpha$  and PGC1 $\beta$   
270 mRNA expression during the brown adipogenesis ( $p < 0.05$ ) (**Figure 4B**). Considered together,  
271 these data indicated that Cy-3-glu positively regulated BAT gene expression. Furthermore, the  
272 expression of NRF1 was significantly increased upon Cy-3-glu treatment ( $p < 0.05$ ) (**Figure 4C**).  
273 In parallel, we observed that Cy-3-glu significantly increased mitochondrial number ( $p < 0.05$ )  
274 (**Figure 4D**). These results indicated that Cy-3-glu significantly increased mitochondrial copy  
275 number during brown adipogenesis. An important characteristic of brown fat cells is their  
276 extraordinarily high rates of oxygen (O<sub>2</sub>) respiration, and uncoupled respiration in response to

277 FCCP in particular. As shown in **Figure 4E**, O<sub>2</sub> consumption was significantly increased by  
278 Cy-3-glu treatment at the basal state ( $p < 0.05$ ). It increased further in response to FCCP  
279 stimulation ( $p < 0.05$ ). These results suggest that Cy-3-glu could effectively improve the  
280 respiratory function of brown fat cells.

281

## 282 **Discussion**

283 Our data demonstrate that the ME and MWE increase the number of mitochondria, the expression  
284 levels of thermogenic genes such as UCP1, PGC1 $\alpha$ , and PRDM16, and the oxphos protein levels  
285 on the mitochondria membrane of brown adipocytes during brown adipogenesis. These effects are,  
286 at least in part, mediated by Cy-3-glu—an anthocyanin from ME and MWE.

287 ME has beneficial effects on metabolic syndrome through an unknown mechanism<sup>6</sup>. It may be  
288 possible that these beneficial effects are associated with brown adipose tissue mitochondrial  
289 function. ME reduces fasting blood sugar in type 2 diabetic patients<sup>23</sup>. This has a positive effect  
290 on various (patho) physiologic conditions including hypertension, hyper-glycemia, and  
291 hyper-lipidemia.

292 In addition, overweight individuals that received ME for three months lost 10% of their initial  
293 body weight<sup>6</sup>. ME has also been shown to inhibit lipogenesis and promote lipid clearance<sup>24</sup>. Our  
294 data demonstrated that the ME and MWE increased the number of mitochondria, the expression  
295 levels of thermogenic genes such as UCP1, PGC1 $\alpha$ , and PRDM16 expression and oxphos  
296 protein levels on the mitochondria membrane in brown adipocytes during brown adipogenesis.  
297 These effect at least in part, mediated by Cy-3-glu, the main anthocyanin from ME and MWE.

298 Several interesting compounds including resveratrol were identified during ME analysis<sup>25</sup>. An

299 animal study showed that long-term treatment with resveratrol dramatically improves  
300 dyslipidemia and hyperinsulinemia<sup>10</sup>. Mulberry fruits contain large amounts of anthocyanin  
301 pigments such as Cy-3-glu and Cy-3-rut<sup>26</sup>, which have both antioxidant and anti-inflammatory  
302 actions<sup>3</sup>. Anthocyanin has been shown to block lipid accumulation, and thereby decrease body  
303 weight gain in a high fat diet<sup>27</sup>. Our results consistently indicate that as an active constituent,  
304 Cy-3-glu could significantly ( $p < 0.05$ ) increase mitochondria copy number and O<sub>2</sub> consumption  
305 during brown adipogenesis. The HPLC data (**Table 1**) suggested that the concentration of  
306 Cy-3-glu (10  $\mu$ M) was higher than the concentration in ME/MWE at 10  $\mu$ g/mL. However, our  
307 results demonstrated that both ME/MWE (10  $\mu$ g/mL) and Cy-3-glu (10  $\mu$ M) could significantly ( $p$   
308  $< 0.05$ ) up-regulate UCP1, PGC1 $\alpha$ , PRDM16, Tfam and NRF1 gene expression levels and  
309 increase the number of mitochondria (**Figure 2, Figure 3, and Figure 4**). In addition to Cy-3-glu,  
310 there were a number of other bioactive substances (such as resveratrol and Cy-3-rut) in  
311 ME/MWE<sup>25-26</sup>. Therefore, other bioactive compounds in ME/MWE may work in concert with  
312 single purified Cy-3-glu to improve BAT activity.

313 It has been suggested that ME could be involved in mitochondrial function<sup>17</sup>. BAT is  
314 characterized by multi-locular lipid droplets and is enriched with mitochondria; the total weight of  
315 BAT in man is around 50 g<sup>29</sup>. As a thermogenic organ, BAT contributes 20% of the total resting  
316 energy expenditure when maximally stimulated<sup>30</sup>. Cold exposure dramatically activates BAT and  
317 clears excessive triglycerides in the plasma by increasing lipid uptake into BAT improving energy  
318 metabolism and weight loss<sup>31-32</sup>.

319 These results suggest that the increase in BAT thermogenic function could contribute to the  
320 clearance of excessive lipid contents. Our results indicated that both ME and MWE increased

321 mitochondria copy number and mitochondrial membrane protein expression during brown  
322 adipogenesis (**Figure 3**). However, ME and MWE did not accelerate brown adipogenesis *in vitro*  
323 without significant changes in the expression of adipogenic genes (**Figure 2**). Our results  
324 highlight that ME and/or MWE might improve BAT function by increasing mitochondria number.  
325 Future studies should specify which compositions from ME and MWE would be beneficial for  
326 improving BAT activity.

327 In this study, we demonstrated that ME regulated mitochondria function at least in part through  
328 the p38 pathway (**Figure 3E**). P38 has previously been identified as an inducer of UCP1<sup>33</sup>, and  
329 this report provides evidence that the p38-AMPK-PGC1a pathway could regulate mitochondrial  
330 function<sup>33</sup>. Our results also confirmed that ME could increase p38 phosphorylation and  
331 mitochondrial function.

332 In conclusion, we show that ME and MWE could increase mitochondria number during brown  
333 adipogenesis. These results may open new avenues to treat obesity and attendant disease.

434 **Figure 1.** A representative HPLC chromatogram of mulberry extract (A) and mulberry wine extract (B) with  
435 peaks corresponding to cyanidin-3-glucoside (1) and cyanidin-3-rutinoside (2).

436

437 **Figure 2.** Effects of ME and MWE on C<sub>3</sub>H<sub>10</sub>T<sub>1/2</sub> cell viability and brown adipogenesis. The MTT assay shows  
438 that ME and/or MWE inhibits the growth of C<sub>3</sub>H<sub>10</sub>T<sub>1/2</sub> cells in a dose-dependent manner (A). ME or MWE  
439 treatment did not show significant change in the formation of mature adipocytes (B). The expression levels of  
440 adipogenic marker genes are shown in (C). ME or MWE significantly increased ( $p < 0.05$ ) the expression levels  
441 of fatty acid oxidation related genes such as PGC1 $\alpha$ , PRDM16, CPT1 $\alpha$  (D), and brown adipose tissue specific  
442 gene UCP1 (E) during brown adipogenesis. ME, mulberry extract; MWE, mulberry wine extract.

443

444 **Figure 3.** ME or MWE increase mitochondrial copy number and increase p38 MAPK phosphorylation. Tfam  
445 and NRF1, mitochondrial biogenic genes, were significantly increased ( $p < 0.05$ ) after treatment with ME (A)  
446 and MWE (B). Mitochondrial copy number was significantly increased ( $p < 0.05$ ) by both ME and MWE (C).  
447 The mitochondrial oxphos complex proteins were also significantly increased ( $p < 0.05$ ) in both ME and MWE  
448 treated groups (D). The expression levels of proteins involved in insulin signaling were analyzed after ME or  
449 MWE treatment. The phosphorylation of p38 (P-p38) was significantly increased ( $p < 0.05$ ) after the ME  
450 treatment (E). \* The number shown in Figure 3D and 3E is the intensity value of the band. The asterisk shown  
451 in Fig. 3E indicates the top bands for the p-AMPK. ME, mulberry extract; MWE, mulberry wine extract.

452

453 **Figure 4.** Cyanidin-3-glucoside increased the mitochondrial copy number and enhanced cellular oxygen  
454 consumption. Cyanidin-3-glucoside significantly increased ( $p < 0.05$ ) the expression levels of brown adipose  
455 tissue specific gene UCP1 (A) and fatty acid oxidation related genes such as PRDM16, PGC1 $\alpha$ , and PGC1 $\beta$  (B)

456 during brown adipogenesis. NRF1 was significantly increased ( $p < 0.05$ ) after treatment with  
457 cyanidin-3-glucoside (C). Mitochondrial copy number was significantly increased ( $p < 0.05$ ) by  
458 cyanidin-3-glucoside (D). Cyanidin-3-glucoside significantly increased ( $p < 0.05$ ) the total and uncoupled  
459 respiration of BAT-cMyc cells (E).

**Table 1.** Compositional analysis of ME and MWE.

Ingredients	Mulberry Extract (mg/g)	Mulberry Wine Extract (mg/g)
Total phenolics	696.5 ± 33.9	876.2 ± 36.1
Total anthocyanin	106.58 ± 3.34	65.69 ± 2.78
Cyanidin-3-glucoside	69.93 ± 1.31	8.50 ± 0.12
Cyanidin-3-rutinoside	32.05 ± 0.69	50.22 ± 0.63

ME, mulberry extract; MWE, mulberry wine extract.
