Accepted Manuscript

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this *Accepted Manuscript* with the edited and formatted *Advance Article* as soon as it is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

This paper deals with the basicity, both in the gas phase and in aqueous solution, of a set of 150 pyrazoles covering a range of about $200 \text{ kJ}\cdot\text{mol}^{-1}$ in proton affinity and 10-15 pK_a units. There are 63 NH-pyrazoles, in many cases, with two different tautomers, and 87 N-substituted pyrazoles. The gas phase results are well reproduced by DFT theoretical calculations when the less stable tautomers are removed. The pK_a values to be reproduced adequately by the calculations need not only to remove some tautomers but to use dummy variables accounting for the protonation on exocyclic amine groups and the conformation of 5-phenyl groups. Using these restrictions a large number of unknown pK_a s can be predicted and a few errors corrected.

1. Introduction

Amongst the physicochemical properties of drugs (water solubility, partition coefficient, crystal structure, stereochemistry), related to ADMET (Absorption, Distribution, Metabolism, Excretion)¹ and to SAR (Structure Activity Relationships)² and QSAR (Quantitative Structure Activity Relationships),³ one of the most important is their acid-base characteristics. The Lipinski's "rule of five" state that an orally active drug should have no more than five hydrogen bond (HB) donors (HBD) and no more than ten HB acceptors (HBA).⁴ Since HB can be considered as the initial step of protonation,⁵ these rules are related to the acidity and the basicity of drugs. Besides, the great majority of drugs contain ionizable groups, most being basic while only some are acidic.

The pyrazole skeleton is very common in a great variety of drugs as has been reported in several books and reviews.⁶ Furthermore, some of us have been the main contributors to the determination of the pK_a ,^{7,8,9,10,11} and to the gas-phase basicity of pyrazoles, both experimental^{12,13,14,15,16,17,18,19,20,21,22} and theoretically.^{23,24,25,26} Therefore, we decided to carry out a theoretical study of the basicity of a large family of pyrazoles (150) both PA and pK_a (note that the collection is incomplete, only 68 PAs and 156 pK_a s).

2. Computational methods

The geometries of pyrazoles (Pz) and pyrazolium cations (PzH⁺) have been fully optimized using the functional B3LYP²⁷ and the 6-311++G(d,p) basis set²⁸ as implemented in the Gaussian 09 package (the coordinates of all the optimized geometries are gathered in the Supporting Information).²⁹ The minimum energy structure of all compounds was characterized by frequency analysis. The solvent effects have been evaluated by reoptimizing the structures at B3LYP/6-311++G(d,p) level and the Self-Consistency Reaction Field (SCRf) method,³⁰ based on the Polarized Continuum Model (PCM) of Tomasi and co-workers,³¹ in water as solvent using the standard parameters provided by the Gaussian-09 program.

Scheme 1 shows the acid dissociation of a protonated pyrazole (PzH⁺) into its conjugated base, neutral pyrazole (Pz), and a free proton (H⁺). The pK_a value of an acid is defined as shown in the equation 1. Here, ΔG_{aq} was directly obtained as the difference of the free Gibbs energies of the products and reactants, as indicated in equation 2. Thus, the G_{aq} value of each species can be obtained by adding the solvation energy (ΔG_s) to the free Gibbs energy in gas phase (G_{gas}) (3).

Scheme 1. The species involved.

$$\text{p}K_{\text{a}} = \frac{\Delta G_{\text{aq}}}{RT \ln 10} \quad (1)$$

$$\Delta G_{\text{aq}} = G_{\text{aq}}(\text{Pz}) + G_{\text{aq}}(\text{H}^+) - G_{\text{aq}}(\text{PzH}^+) \quad (2)$$

$$G_{\text{aq}} = G_{\text{gas}} + \Delta G_{\text{s}} \quad (3)$$

The proton free energy in aqueous solution is uncertain. Thus, we decided to use experimental values for this variable. The experimental estimations of the solvation energy of the free proton range from -1062.7 to -1112.5 kJ·mol⁻¹. Most programs for calculating solvent effects (SMD,^[32] COSMO^[33]) use the last value.^[34]

With the aim of minimize possible errors we calculated two pK_a values for each Pz by using different ΔG_s data according to literature, *i.e* the highest calculated value ΔG_s = -1112.5 kJ·mol⁻¹ and the mean value of the range, ΔG_s = -1085.7 kJ·mol⁻¹.³⁵

$$\text{p}K_{\text{a}}(\text{Pz}) = \frac{G_{\text{aq}}(\text{Pz}) + \Delta G_{\text{s}}(\text{H}^+) - G_{\text{aq}}(\text{PzH}^+)}{RT \ln 10} \quad (4)$$

Table 1 contains all the data for the following discussion and Table S1 of the Electronic supplementary information (ESI) contains supplementary columns with intermediate data. For some substituents we have used simplified codes: they are reported in Fig. 1.

Fig 1 Structure of some substituents.

Table 1 Collection of data related to pyrazoles **1** to **150**. All pK_a values from reference ¹⁰ save compounds **55** and **56** (see footnote k). $\Delta H_{\text{Gas}} = H_{\text{Gas}}(\text{Pz}) - H_{\text{Gas}}(\text{PzH}^+)$; $\Delta G_{\text{Gas}} = G_{\text{Gas}}(\text{Pz}) - G_{\text{Gas}}(\text{PzH}^+)$; $\Delta H_{\text{Aqueous}} = H_{\text{Aqueous}}(\text{Pz}) - H_{\text{Aqueous}}(\text{PzH}^+)$; $\Delta G_{\text{Aqueous}} = G_{\text{Aqueous}}(\text{Pz}) - G_{\text{Aqueous}}(\text{PzH}^+)$. **c** compounds (**62**, **98**, **117**, **132**, **148**) correspond to protonation on the amino group.

3. Results and discussion

3.1. The gas phase.

3.1.1. The tautomerism of pyrazoles. Neutral molecules.

We have represented in Fig. 2 the pyrazole tautomers when they are different, i.e., when $R^3 \neq R^5$. We have labeled **a** the most abundant tautomer in the gas phase according to our calculations, even if in some cases they differ from those reported in the literature. However, note that most literature results come from condensed phases (solution and solid state)³⁶ and will be discussed in section 3.2 (water solution).

Fig. 2 Pairs of tautomeric pyrazoles.

We have reported in Table 2 the differences in energy between tautomers **a** and **b** as well as other properties related to the tautomerism of pyrazoles.

Table 2 Differences in energy including the zero-point vibrational energy (ZPVE) correction ($\text{kJ}\cdot\text{mol}^{-1}$) between tautomers **a** and **b** as well as the effect of the water solvation defined as $\Delta\Delta E$ (water–gas). Columns: 1st is the compound number of Table 1; 2nd is the name of the pyrazole tautomer **a**; 3rd specifies the substituent at position 3 of tautomer **a**; 4th is the difference in energy between the **a** (0 by definition) and **b** tautomers in the gas phase; 5th is the corresponding values for the water solution (PCM) but here **a** is not always the most stable tautomer (negative values correspond to the **b** tautomer being more stable); 6th is the difference in energy, $\Delta\Delta E$, when tautomer **a** is the most stable in the gas phase and in water while the 7th is the difference in energy (actually a sum), $\Delta\Delta E$, when tautomer **a** is the most stable in the gas phase and tautomer **b** in water; 8th and 9th reports the populations of tautomers **a** and **b** in the gas phase and in water, respectively; 10th summarizes the calculated results of columns 6 and 7; finally, 11th and 12th report the experimental results. 11th also contains a comment about the agreement or not between columns 10 and 11.

^a Agree; ^b Disagree.

Using the Boltzmann equation ($T = 298 \text{ K}$) we have calculated the populations of tautomers. We will comment here Table 2 gas phase results concerning tautomerism in what concerns some inversion in stability of the phenyl group at positions 3(5). Tautomer **a** (3-phenyl) is the most stable for compounds **45**, **49** and **50** without substituents at position 4; on the other hand, tautomer **b** (5-phenyl) is the most stable for compounds **46**, **47**, **48**, **51** and **52**. This is related to the conformation of the 3-phenyl group in **a** tautomers: for the first three compounds the dihedral angle between rings ranges from 0 to 4° while for the last five ones it ranges from 29 to 33° (see Table S2). A planar phenyl group prefers the 3-position while a twisted one prefers the 5-position.

3.1.2. The tautomerism of pyrazoles. Protonated molecules.

Concerning the structure of the cations, for all of them we have calculated the structures resulting from the protonation on the N2 nitrogen atom (pyrazolium salts); besides, for six of them, we have also calculated the cations (pyrazoles **c**) resulting from the protonation of the functional group (Fig. 3), mainly of the amino group (ammonium salts).

Fig. 3 Cations protonated on the amino and amidine groups.

In Table 3 are reported the differences in stability ($\text{kJ}\cdot\text{mol}^{-1}$) of the cations corresponding to the pyrazoles of Fig. 3. The 7th column indicates the tautomer (**c** or **a**) found experimentally.

Table 3 Relative stabilities of N_2 vs. functional group cations including the ZPVE correction. The values of ΔH_{Gas} for **c** cations of Table 1 are also reported.

No	Name	ΔH_{Gas} ($\text{kJ}\cdot\text{mol}^{-1}$)	gas phase		water		$\Delta E E \text{ a}^a$	Exp.	Ref.
			$\text{N}_2 \text{ a}$	subs. c	$\text{N}_2 \text{ a}$	subs. c

---	aniline	871.65 ^b						---	

^a Water effect on the stability of tautomer **a** calculated as **c** – **a**; ^b Experimental value, $876.55 \text{ kJ}\cdot\text{mol}^{-1}$.³⁶

In the gas phase, excluding the very basic amidine derivative **150**, all aminopyrazoles, either 4-NH₂ or 1-NH₂, protonate on the ring. The protonation on the C-amino group lead to compounds having similar basicities than aniline (Table 3); the N-amino group decreases considerably the basicity of the pyrazole ring compared with the effect of the 4-amino one.

3.1.2. Proton affinities.

For proton affinities (PAs), we have used all the NIST values that differ from those published in our papers by being corrected for temperature effects.³⁹ There are some values that were not reported in the NIST database (Table S1). We have transformed these data into PA NIST corr. empirically by means of equation 5:

$$\text{PA NIST corr.} = -(63 \pm 35) + (1.07 \pm 0.04) \text{ PA}, n = 14, R^2 = 0.985 \quad (5)$$

We have then compared the PA NIST corr. with the calculated ΔH values:

$$\text{PA NIST corr.} = (67 \pm 13) + (0.92 \pm 0.01) \Delta H, n = 69, R^2 = 0.984 \quad (6)$$

This is already acceptable but the correlation improves eliminating the less stable **b** tautomers:

$$\text{PA NIST corr.} = (65 \pm 11) + (0.93 \pm 0.01) \Delta H, n = 57, R^2 = 0.990 \quad (7)$$

Fig. 4 is the plot corresponding to eq. 7.

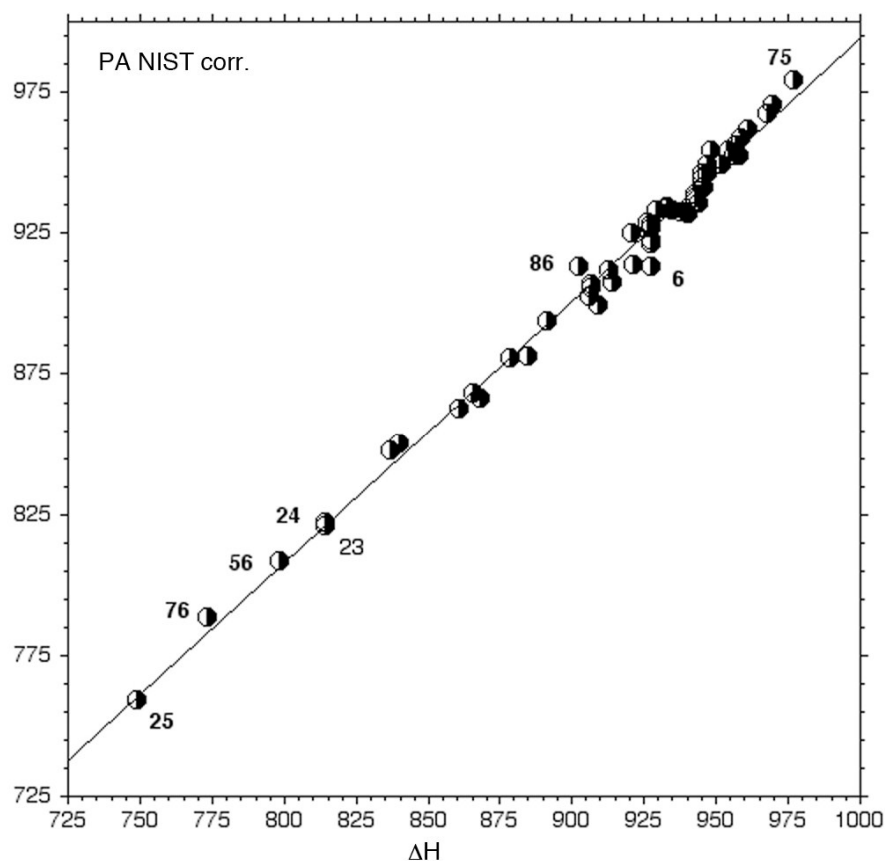

Fig. 4 Plot corresponding to eq. (7) with worse points (**6**, **75**, **86**) and less basic pyrazoles (**23**, **24**, **25**, **56**, **76**).

We have repeated this analysis using only the NH-derivatives:

$$\text{PA NIST corr.} = (79 \pm 15) + (0.91 \pm 0.02) \Delta H, n = 42, R^2 = 0.986 \quad (8)$$

$$\text{PA NIST corr.} = (71 \pm 14) + (0.91 \pm 0.02) \Delta H, n = 30, R^2 = 0.992 \quad (9)$$

The elimination of the less abundant tautomers improves the correlations (compare eqs. 7 vs. 6 and 9 vs. 8) but the quality of the regressions is not sufficient to determine the proportions of both tautomers (the tautomeric equilibrium constant, K_T) since the largest deviations are found for compounds, like **6** (4-adamantyl-1*H*-pyrazole-3,5-dicarboxylic acid diethyl ester) and **86** (diethyl ester of 1-methyl-1*H*-pyrazole-3,5-dicarboxylic acid), that are not involved in tautomerism. There is no anomaly in our gas phase calculations but there is a significant intercept of about $65 \text{ kJ}\cdot\text{mol}^{-1}$, that it is related to the less basic pyrazoles (bottom-left of Fig. 4); removing them the intercept decreases to $19 \text{ kJ}\cdot\text{mol}^{-1}$.

3.2. The aqueous phase.

We will now discuss the basicity of pyrazoles in water at $25 \text{ }^\circ\text{C}$ (thermodynamic values) of Table 1. When the pK_a s have been determined at another temperature, for instance at $20 \text{ }^\circ\text{C}$, or in the presence of small amounts of a co-solvent, for instance 5-10% of methanol or ethanol, these values have been empirically corrected.^{9,10}

3.2.1. The tautomerism of pyrazoles. Neutral molecules.

On going from the gas phase to water solution (Table 2) in most cases (26) the predominant tautomer **a** remains unchanged but in several other (13) an inversion is observed and tautomer **b** becomes the most stable. Considering only the effects $> |2| \text{ kJ}\cdot\text{mol}^{-1}$, with some substituents, the stability of tautomer **a** increases, this is the case of Cl (**29**, **37**), Br (**34**, **38**, **42**), planar phenyl (**49**, **50**) and CF_3 (**55**) while for other it decreases: ethyl (**3**), *t*-butyl (**4**), twisted phenyl (**46**, **47**, **51**, **52**), cyclopropyl (**44**), ethoxycarbonyl (**58**, **60**), amino (**61**) and specially nitro (**23**).

The experimental data on some of these compounds come from rather different conditions, solution in solvents as different as chloroform, DMSO, water and others, as well as solid state (NMR and crystallography, usually only one tautomer). Even though, the agreement (Table 2) is satisfactory, with very few exceptions. The most evident is **8** where the calculations predict tautomer **a** to be the most stable by $1.32 \text{ kJ}\cdot\text{mol}^{-1}$, whereas the experimental result corresponds to the **b** tautomer but it corresponds to a crystal structure.

Using ΔG instead of ΔE does not change the main conclusions because both parameters are correlated:

$$\Delta G = (0.99 \pm 0.04) \Delta E, n = 39, R^2 = 0.955 \quad (10)$$

3.2.2. The tautomerism of pyrazoles. Protonated molecules.

As reported in Table 3, water causes a truly enormous decrease (between 38 and $59 \text{ kJ}\cdot\text{mol}^{-1}$) of the stability of tautomer **a** in the case of aminopyrazoles. The calculations reproduce adequately the behavior of 1-aminopyrazole (**148**), but in the case of *C*-aminopyrazoles, the calculations reproduce the greater stability of the ammonium salt **132c** but not those of the remaining compounds, where differences of 7 - $13 \text{ kJ}\cdot\text{mol}^{-1}$ in favor of **a** tautomers are calculated.

3.2.3. Thermodynamic pK_a values.

The first and most obvious observation of Table S1 is the effect of 4.69 pK_a units due to the value used for the free energy of the H^+ . The following points have to be removed **62**, **98**, **117** and **132** all of them 4-aminopyrazoles because it has been determined experimentally that they do not protonate on the pyrazole ring but on the amino group,³⁷ the values for the protonation on the amino group are consistent with the experimental pK_a . In the case of 1-aminopyrazole (**148**) it protonates on the pyrazole ring,³⁸ as the agreement with the experimental pK_a confirms. After several attempts (see S3 in the ESI), we found that the best equation is the following one (using pK_a^i instead of pK_a^j adds an intercept related to the 4.69 difference):

$$\text{Exp. } pK_a = (0.53 \pm 0.01) \text{ Calc. } pK_a^i - (0.81 \pm 0.05) \text{ NR} - (0.37 \pm 0.12) \text{ 5-Ph} + (4.30 \pm 0.21) \text{ NH}_3^+, n = 148, R^2 = 0.979 \quad (11)$$

i. All **b** tautomers clearly less stable than the **a** ones have been removed in equation (11): **15b** (camphopyrazole tautomer *2H* is much more stable than *1H*), **29b**, **30b**, **34b**, **37b**, **38b**, **42b** (all of them 5-halo substituted) and **55b** (5- CF_3 substituted).

ii. All other effects being equal, experimental values are in average 53% of the calculated ones.

iii. NR is a dummy variable that has the value 0 for the NH and the value 1 for the NR pyrazoles. The *N*-unsubstituted pyrazoles are weaker bases than the corresponding *N*-substituted ones. The decrease of 0.81 pK_a units is related to the statistical effect that amounts to 2 for NH-pyrazoles having identical substituents at positions 3 and 5.^{9,10,40}

iv. 5-Ph is a dummy variable that has the value 0 for all pyrazoles save those having a 5-phenyl substituent. The origin of the small but significant effect, -0.37 ± 0.12 , is probably related to the conformation of the phenyl ring that could not be well reproduced by the calculations in water both for the neutral and the protonated forms.

v. The very big effect necessary to account for the pK_a of the 4-aminopyrazoles (**62**, **98**, **117** and **132**) is related to the NH_3^+ cation, not only the statistical factor of 3 but a different kind of structure. They are more related to aniline that we have calculated at the same level (equation 12).

$$\text{Exp. } pK_a = (4.4 \pm 0.3) + (0.39 \pm 0.08) \text{ Calc. } pK_a^j - (0.53 \pm 0.25) \text{ NR}, n = 5, R^2 = 0.947 \quad (12)$$

Two outlier points remain (Fig. 5):

Exp. $pK_a = -8.23$
Fitted $pK_a = -5.06$

Exp. $pK_a = 2.94$
Fitted $pK_a = -1.57$

Fig. 5 Outliers.

The pK_a value of **56** has not been measured being too weak but estimated from its acid (proton loss) pK_a ; compound **146** is an azolide⁴¹ and therefore very easy to hydrolyze: both experimental values are probably wrong.

This equation predicts for **150**, an important compound,⁴² a pK_a of 0.92 if protonates on N2 and 6.96 if protonates on the amidine (the N1 atom of pyrazole has its lone pair

involved in the aromatic sextet, thus compound **150** is not a guanidine). Although it is clear that it will behave as a guanidine, the second value should be considered with care in case **150** does not follow eq. (11) similarly to what happens to 4-aminopyrazoles.

Eq. 11 is useful to predict values and we have added them to the last column of Table 1 but it is not entirely satisfactory since it has a slope of 0.53, that is, the calculated pK_a s are almost twice the experimental ones. However, an examination of the literature in what concerns pK_a calculations show that the reported results are not better than ours, for instance, the mean absolute deviation (MAD) for 30 organic molecules⁴³ and for 55 neutral organic and inorganic acids³⁵ using the direct method (like us) is between 2.5 and 3 pK_a units, and for our much larger set is 1.9 pK_a units. Using linear correlations, other authors have found R^2 values ranging from 0.720 to 0.908.⁴⁴ Only for small sets (13 heterocyclic compounds) bearing only H, CH_3 and Cl substituents better correlations have been found.⁴⁵

4. Concluding remarks

We have studied a large variety of compounds that although homogeneous in structure, being all pyrazoles, differ in their protonation sites and in their tautomeric stability. The range of experimental PA is $208.1 \text{ kJ}\cdot\text{mol}^{-1}$ (from 759.4 to 967.5) and that of pK_a s is 10.28 pK_a units (from -4.71 to $+5.57$), range that increases if predicted values are included (15.80 , from -8.82 to $+6.98$).

We have chosen the more demanding approach, leaving aside methods, like the isodesmic and other thermodynamic cycles, that use a molecule, generally the parent compound, as reference.^[34,46,47] Our results prove that this restriction is not absolutely necessary.

Although most authors prefer for the proton solvation free energy the value of $-1112.5 \text{ kJ}\cdot\text{mol}^{-1}$,^[32,33,34] we have obtained better results with $-1085.7 \text{ kJ}\cdot\text{mol}^{-1}$, further works are necessary to decide between both values.

Even if the main purpose of this paper is the calculation of acid-base properties of pyrazoles, it also provides information to the related topic of NH-pyrazoles tautomerism (remember that both tautomer share the same conjugated acid, the pyrazolium cation). Tautomerism of pyrazoles is still a matter of some confusion (see, ref.⁴⁸ for a paper where only one pyrazole tautomer is considered in the ground state without any proof).

Acknowledgements

This work has been supported by the Spanish Ministerio de Economía y Competitividad (CTQ2012-35513-C02-02) and Comunidad Autónoma de Madrid (S2013/MIT-2841, Fotocarbon). Computer, storage and other resources from the CTI (CSIC) are gratefully acknowledged. One of us (M.M.-L.) benefits from a contract from the Ministerio de Economía y Competitividad.
