 4 **electrode shows superior rate capability and cycling** 43  
 5 **performance to bare TiO<sub>2</sub> and Fe<sub>2</sub>O<sub>3</sub> electrodes.** 44  
 45  
 46  
 6 TiO<sub>2</sub> with various morphologies such as nanotubes,<sup>1</sup> nanowires,<sup>2</sup>  
 7 nanosheets,<sup>4</sup> mesoporous microspheres<sup>5</sup> and so on have been  
 8 extensively studied as the candidate for the next-generation anode  
 9 materials. Amongst them, nanosheet TiO<sub>2</sub> with the two-dimensional  
 10 morphology similar to graphene<sup>6</sup> shows efficient rate and cycling  
 11 performance for rechargeable lithium-ion batteries (LIBs).<sup>7</sup>  
 12 However, it is well known that the TiO<sub>2</sub> possesses relatively low  
 13 theoretical capacity of 335 mAh g<sup>-1</sup> even with the maximum  
 14 accommodation of one Li<sup>+</sup> per TiO<sub>2</sub> unit (Li<sub>1.0</sub>TiO<sub>2</sub>),<sup>10</sup> which  
 15 seriously hinders its potential large-scale applications  
 16 commercialization. To circumvent above issues, a number  
 17 of metallic oxides (MO) with high specific capacity (700-1000 mAh  
 18 g<sup>-1</sup>) were therefore used to synthesize hybrid TiO<sub>2</sub>-MO  
 19 nanocomposites. By this way, the advantages of the high capacity  
 20 for MO and the electrochemical stability of TiO<sub>2</sub> will  
 21 be incorporated together. For example, it has been reported by Zeng  
 22 group that highly uniform TiO<sub>2</sub>/SnO<sub>2</sub>/carbon hybrid nanofibers  
 23 showed enhanced lithium storage performance.<sup>11</sup> On the other hand,  
 24 Fe<sub>2</sub>O<sub>3</sub> nanorods were also grafted within TiO<sub>2</sub> nanotubes and have  
 25 impressed cycling performance by Lou's group.<sup>12</sup> Most recently,  
 26 Co<sub>3</sub>O<sub>4</sub>, Fe<sub>2</sub>O<sub>3</sub>, Fe<sub>3</sub>O<sub>4</sub> and CuO grown on TiO<sub>2</sub> fibres with  
 27 hierarchical heterostructures have also been fabricated by Wang's  
 28 group and displayed improved electrochemical performance.<sup>13</sup>  
 29 Among above mentioned materials, α-Fe<sub>2</sub>O<sub>3</sub> with higher theoretical  
 30 capacity (1007 mAh g<sup>-1</sup>) than commercial graphite-based (372 mAh  
 31 g<sup>-1</sup>) anode materials,<sup>14,15</sup> low cost and environmental friendliness,  
 32 inevitably has received considerable interests.<sup>16-17</sup> Nevertheless,  
 33 the best of our knowledge, there has been no report about Fe<sub>2</sub>O<sub>3</sub>  
 34 nanorods anchored on two dimensional (2D) TiO<sub>2</sub> nanosheets so far,  
 35 in which TiO<sub>2</sub> nanosheets have been considered as the state-of-the-  
 36 art materials for LIBs.<sup>7-9</sup>  
 37 Herein, for the first time, we developed a facile hydrothermal  
 38 method instead of conventional template and electrodeposition  
 39 strategies to successfully fabricate hierarchical three-dimensional

(3D) TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> core-shell nanoframework arrays. To overcome  
 the problems of the large volume expansion and grain aggregation  
 for Fe<sub>2</sub>O<sub>3</sub>,<sup>18</sup> mesoporous TiO<sub>2</sub> nanosheets directly grown on Ti  
 substrate were followed by the uniform deposition of Fe<sub>2</sub>O<sub>3</sub>  
 nanorods, in which the nanorod structure of Fe<sub>2</sub>O<sub>3</sub> not only provides  
 direct and open channels for Li ions, but also it can accommodate  
 the volume expansion in virtue of the space between and within the  
 mesoporous nanorod structure.<sup>16</sup> Besides, the 3D TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub>  
 nanoframework arrays possessing synergetic effect as the electrode  
 without any conductive agent and binder demonstrate potential  
 applications.<sup>19,20</sup> The synergetic effect mentioned above can be  
 summarized as follows. Firstly, the aggregation and volume  
 expansion of Fe<sub>2</sub>O<sub>3</sub> can be effectively avoided with the mesoporous  
 TiO<sub>2</sub> nanosheets as the scaffold in the process of lithium/delithium  
 reaction.<sup>21</sup> Simultaneously, the free space between nanorod and  
 mesoporous structures can provide open channels and more contact  
 area for the transportation of lithium ions and electrons, allowing  
 superior lithium storage performance. Secondly, the deposition of  
 Fe<sub>2</sub>O<sub>3</sub> nanorods on TiO<sub>2</sub> nanosheets not only showed enhanced  
 capacity, but also well integrated the electrochemical advantages of  
 these two functional materials in the form of hierarchical structure.

Scheme. 1 shows the evolution process of hierarchical  
 TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> nanoframework arrays. In the first step, TiO<sub>2</sub>  
 nanosheet arrays were prepared via the routine hydrothermal  
 reaction reported previously.<sup>22</sup> Subsequently, 3D TiO<sub>2</sub>@FeOOH  
 nanoframework arrays were synthesized with the hydrolysis of FeCl<sub>3</sub>  
 and the final hierarchical TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> arrays were in-situ formed  
 after the calcination at 500 °C for 1h. The detailed experimental  
 process for the preparation is shown in supporting information  
 (ESI†).

Surprisingly, it is found that the morphology of TiO<sub>2</sub> arrays can be  
 controlled by varying the amount of NaCl (Fig. S1, ESI†) in the  
 process of hydrothermal reaction. Scanning electron microscopy  
 (SEM) measurement was introduced to observe the morphology of  
 TiO<sub>2</sub> arrays in different conditions. It can be seen that the TiO<sub>2</sub>  
 nanosheets were formed when the concentration of NaCl was 0 and  
 1 M, and the morphology of the above two samples almost had no  
 difference according to the SEM images shown in Figs. S1a† and  
 S1b†. However, both TiO<sub>2</sub> nanowires and nanosheets were prepared  
 in the meantime (seen in Fig. S1c†) when the concentration of NaCl  
 increased to 2 M. There was only TiO<sub>2</sub> nanowire clearly observed in

1 Fig. S1d† if the concentration of NaCl was 3 M. Therefore, 50  
 2 content of NaCl had great effect on the morphology of TiO<sub>2</sub> arrays, 51  
 3 which controlled the nucleation and growth processes.<sup>23</sup> 52  
 4

5  
 6 **Scheme 1.** Schematic illustration for the fabrication of 3D  
 7 TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> nanoframework arrays.

8 It is fortunately found that the morphology of TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> arrays  
 9 were also varied with different amounts of FeCl<sub>3</sub>·6H<sub>2</sub>O and Na<sub>2</sub>SO<sub>4</sub>  
 10 as shown in Fig. S2†. When the addition of FeCl<sub>3</sub>·6H<sub>2</sub>O was 9.3 mM  
 11 and 18.6 mM, α-Fe<sub>2</sub>O<sub>3</sub> nanorods with the length of around 100 nm  
 12 and 200 nm were uniformly deposited on TiO<sub>2</sub> nanosheets  
 13 respectively, which can be clearly seen in Figs. S2a–S2d†. If the  
 14 amount of FeCl<sub>3</sub>·6H<sub>2</sub>O increased to 25 mM, however, there was no  
 15 nanosheet observed in Fig. S2e†, which may be due to the excess of  
 16 FeCl<sub>3</sub>·6H<sub>2</sub>O. All of the TiO<sub>2</sub> nanosheets were covered by Fe<sub>2</sub>O<sub>3</sub>  
 17 nanorods and were agglomerated to bunches after calcination (Fig.  
 18 S2f†). Transmission electron microscopy (TEM) analysis was also  
 19 introduced to further investigate the morphology of bare TiO<sub>2</sub>  
 20 nanosheet arrays and 3D TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> arrays. Fig. 1a showed the  
 21 SEM image of TiO<sub>2</sub> nanosheets with size of around 1 μm and  
 22 thickness of 50 nm. However, TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> nanoframework showed  
 23 worm-like morphology with size of ~500 nm after uniformly  
 24 deposited Fe<sub>2</sub>O<sub>3</sub> nanorods (Fig. 1b). The inset is the close  
 25 observation of the single TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> framework, in which Fe<sub>2</sub>O<sub>3</sub>  
 26 nanorods with length of ~200 nm were delicately anchored on the  
 27 TiO<sub>2</sub> nanosheet backbone, leading to the obvious swelling of  
 28 TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> nanoframeworks compared to bare TiO<sub>2</sub> nanosheet  
 29 arrays. The calculated mass ratio of TiO<sub>2</sub> (57.1%) and Fe<sub>2</sub>O<sub>3</sub> (42.9%)  
 30 was obtained by weighing the active materials of TiO<sub>2</sub> and  
 31 TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> respectively through subtracting the mass of substrates.  
 32 The balance (Sartorius, BT 125D) was used to weight the mass.  
 33 From the enlarged TEM image of the single TiO<sub>2</sub> nanosheet in Fig.  
 34 1c, we can conclude that the TiO<sub>2</sub> nanosheets were composed of  
 35 nanoparticles of diameter around 20 nm and possessed mesoporous  
 36 nanostructure. The pore size distribution of TiO<sub>2</sub> nanosheets  
 37 shown in Fig. S3a† and the inset is the TEM image of the individual  
 38 TiO<sub>2</sub> nanosheet. The remarkable lattice fringes with 0.35 nm  
 39 interplanar spacing of anatase TiO<sub>2</sub> were observed via a high-  
 40 resolution TEM (HRTEM) image (Fig. 1d), which corresponded to  
 41 the typical (101) plane. Mesoporous Fe<sub>2</sub>O<sub>3</sub> nanorods with size  
 42 around 200 nm were observed distinctly in the enlarged TEM image  
 43 of TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> (Fig. 1e) and the inset was the full view of the single  
 44 3D TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> composite. These images agreed well with the  
 45 SEM results. N<sub>2</sub> adsorption-desorption curve was introduced to  
 46 further clarify the nanostructure of TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> (Fig. S3b†). Type  
 47 IV curve with H2 hysteresis loop and the pore size distribution  
 48 concentrated at 2~11 nm revealed the mesoporous nanostructure  
 49 of the material. Typical lattice fringes of α-Fe<sub>2</sub>O<sub>3</sub> with interplanar

distance 0.27 nm were shown in the HRTEM image (Fig. 1f), further  
 demonstrating that Fe<sub>2</sub>O<sub>3</sub> nanorods were indeed tightly deposited on  
 TiO<sub>2</sub> nanosheets.

53 The mechanistic comparison of lithium ion diffusion between bare  
 54 TiO<sub>2</sub> nanosheet arrays and the TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> nanoframework arrays is  
 55 depicted in Fig. 2a. It can be clearly seen that there were more direct  
 56 channels for lithium ion diffusion because of the existence of Fe<sub>2</sub>O<sub>3</sub>  
 57 nanorods compared with bare 2D TiO<sub>2</sub>, which thereafter provided  
 58 more contact area between electrolyte and active materials for  
 59 potential high-performance LIBs.<sup>24</sup> It further illustrates the presence  
 60 of synergetic effect in the TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> arrays. The nyquist plots  
 61 (The inset is the magnified nyquist plots and the equivalent circuit  
 62 model) of TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub>, TiO<sub>2</sub> and Fe<sub>2</sub>O<sub>3</sub> electrodes are presented in  
 63 Fig S4a†. Simultaneously, the lithium ion diffusion coefficients of  
 64 TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> ( $D_{Li}=8.5\times 10^{-11}$  cm<sup>2</sup> s<sup>-1</sup>), TiO<sub>2</sub> ( $D_{Li}=2.6\times 10^{-11}$  cm<sup>2</sup> s<sup>-1</sup>),  
 65 Fe<sub>2</sub>O<sub>3</sub> ( $D_{Li}=1.9\times 10^{-11}$  cm<sup>2</sup> s<sup>-1</sup>) were calculated according to the  
 66 relation between low frequency and real resistance in Fig S4b†. The

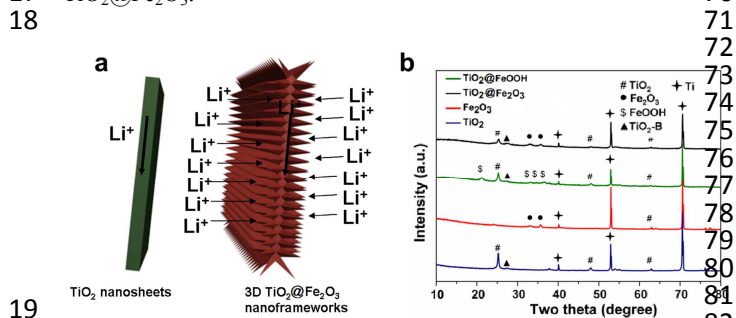

**Fig. 1.** SEM images of (a) TiO<sub>2</sub> nanosheet arrays and (b) TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> arrays (The inset is the magnified image of single worm-like structure); (c) TEM images (The inset is the magnified image of the edge) and (d) HRTEM images of TiO<sub>2</sub> nanosheet arrays; (e) TEM images of TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> arrays (The inset is the magnified image of the edge) and (f) HRTEM image of the anchored α-Fe<sub>2</sub>O<sub>3</sub> nanorods

data indicated the improved lithium ion diffusion after the anchor of Fe<sub>2</sub>O<sub>3</sub> nanorods and verified the mechanism illustrated in Fig. 2a.<sup>25</sup>

X-ray diffraction (XRD) patterns of the prepared Fe<sub>2</sub>O<sub>3</sub> nanorods, TiO<sub>2</sub> nanosheets, TiO<sub>2</sub>@FeOOH (the intermediate of TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub>) and TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> nanoframeworks are displayed in Fig. 2b. There

1 was only typical diffraction peaks of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> (hematite, JCPDS card 54  
 2 no. 330664) for Fe<sub>2</sub>O<sub>3</sub> nanorods, while there were diffraction peaks 55  
 3 ascribed to TiO<sub>2</sub>-B for TiO<sub>2</sub> nanosheets, TiO<sub>2</sub>@FeOOH and 56  
 4 TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> nanoframeworks, which was in accordance with 57  
 5 previous report.<sup>22</sup> Typical reflection peaks of FeOOH (JCPDS card 58  
 6 No.22-0353) for TiO<sub>2</sub>@FeOOH combined with the peaks of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> 59  
 7 for TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> were also detected besides the peaks of anatase 60  
 8 TiO<sub>2</sub> (JCPDS card No.21-1272) and TiO<sub>2</sub>-B, revealing the existence 61  
 9 of well crystallized Fe<sub>2</sub>O<sub>3</sub> nanorods and TiO<sub>2</sub> nanosheets for the first 62  
 10 TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub>. All of the diffraction peaks of TiO<sub>2</sub> nanosheet were 63  
 11 well classified to typical anatase TiO<sub>2</sub> without any purity. TiO<sub>2</sub> 64  
 12 comparison of XRD patterns for TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> prepared with 65  
 13 different amounts of FeCl<sub>3</sub>·6H<sub>2</sub>O and Na<sub>2</sub>SO<sub>4</sub> is shown in Fig. S3 66  
 14 It is obviously seen that with the increased amount of FeCl<sub>3</sub>·6H<sub>2</sub>O 67  
 15 the intensity of the reflection peaks for  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> became stronger 68  
 16 demonstrating the increased content of Fe<sub>2</sub>O<sub>3</sub> in the sample 69  
 17 TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub>. 70

24 **Fig. 2.** (a) Schematic comparison of Li ion diffusion between TiO<sub>2</sub> 84  
 25 nanosheet arrays and TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> arrays. (b) XRD patterns of TiO<sub>2</sub> 85  
 26 nanosheet arrays, pure Fe<sub>2</sub>O<sub>3</sub> nanorods, TiO<sub>2</sub>@FeOOH and final 86  
 27 TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> arrays. 87

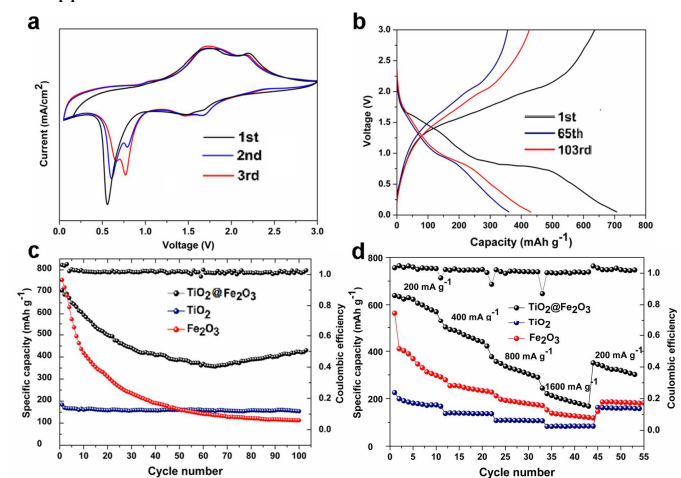

28 In order to thoroughly elucidate the improved electrochemical 24  
 29 performance for the TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> electrode, Fe<sub>2</sub>O<sub>3</sub> nanorod (SEM 25  
 30 image shown in Fig. S6†) and TiO<sub>2</sub> nanosheet arrays were also 26  
 31 prepared to assemble circular electrodes. The optical images of the 27  
 32 prepared samples and bare Ti substrate (Chinese coin for scale bar) 28  
 33 are presented in Fig. S7†. Cyclic voltametry (CV) curves of the 29  
 34 TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> electrode in the initial three charge-discharge cycles 30  
 35 are displayed in Fig. 3 with the scanning rate of 0.5 mV s<sup>-1</sup> in 31  
 36 the window voltage of 0.05~3 V. Typical two cathodic peaks at 1.5 and 32  
 37 0.6 V were shown in the first cycle, corresponding to the process of 33  
 38 reduction for Fe<sub>2</sub>O<sub>3</sub> from Fe<sup>3+</sup> to Fe<sup>2+</sup> and Fe<sup>0</sup> combined with the 34  
 39 formation of SEI film.<sup>16,28-29</sup> There were two oxidation peaks at 1.7 35  
 40 and 2.4 V corresponding to the extraction of Li ions from Fe<sub>2</sub>O<sub>3</sub> and 36  
 41 TiO<sub>2</sub> for TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> electrode. In the second cycle, there was a 37  
 42 slight increase of oxidation peaks at 0.65, 0.8, and 1.7 V with the 38  
 43 lower intensity, indicating the existence of irreversible reaction 39  
 44 ascribed to formation of SEI film.<sup>28,29</sup> The oxidation and reduction 40  
 45 peaks almost had no change in the subsequent cycle, demonstrating 41  
 46 the good reversibility of the TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> electrode. 42

43 The galvanostatic charge-discharge curves of TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> 43  
 44 electrode in the 1st, 65th and 103rd cycles with the voltage window 44  
 45 of 0.05 V~3 V at 200 mA g<sup>-1</sup> are shown in Fig. 3b. The plateau 45  
 46 voltages in the first cycle were in good agreement with the oxidation 46  
 47 and reduction peaks in the above mentioned CVs. The charge- 47  
 48 discharge curves of TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub>, bare TiO<sub>2</sub> and bare Fe<sub>2</sub>O<sub>3</sub> 48  
 49 electrodes at different current densities are presented in Fig. S8† 49  
 50 illustrate the different electrochemical reactions in terms of 50  
 51 lithium/delithium process. The cycling performance of bare TiO<sub>2</sub> 51  
 52 and Fe<sub>2</sub>O<sub>3</sub> electrodes were also introduced to further illustrate 52  
 53 superior cycling performance of the TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> electrode in Fig. 53

3c. TiO<sub>2</sub> nanosheet electrode showed stable cyclability with almost 3c  
 no capacity loss after 100 cycles but with only one-fourth initial 3c  
 capacity. For Fe<sub>2</sub>O<sub>3</sub> electrode, its specific capacity degraded severely 3c  
 through 100 cycles at 200 mA g<sup>-1</sup> since only 112.9 mAh g<sup>-1</sup> 3c  
 remained. In contrast, the TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> electrode had the most 3c  
 excellent cyclability actually with the increasing specific capacity 3c  
 starting from the 67th cycle and still possessed capacity of 430.2 3c  
 mAh g<sup>-1</sup> after 103 cycles. This phenomenon is not uncommon for 3c  
 Fe<sub>2</sub>O<sub>3</sub> and other metal oxide materials.<sup>26-31</sup> It is generally attributed 3c  
 to the formation of polymeric/gel-like film around the active 3c  
 materials caused by the decomposition of the electrolyte at low 3c  
 potential, which enabled the mechanical cohesion and delivered 3c  
 excess capacity through a so called “pseudo-capacity-type” behavior. 3c  
 On the other hand, the synergetic effect of the hybrid materials was 3c  
 also the main reason for the increased capacity as for bare Fe<sub>2</sub>O<sub>3</sub> 3c  
 nanorod arrays, there was no capacity increase observed. The 3c  
 corresponding coulombic efficiency of TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> electrode was 3c  
 almost 100% in the over process. The rate performance of above 3c  
 mentioned three electrodes are presented in Fig. 3d, in which the 3c  
 TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> electrode showed much higher capacity than bare TiO<sub>2</sub> 3c  
 and Fe<sub>2</sub>O<sub>3</sub> electrodes. Nevertheless, the specific capacity for 3c  
 TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> electrode decayed severely in case of different current 3c  
 densities, which might be attributed to the partially irreversible 3c  
 formation of Fe nanoparticles in the initial electrochemical reaction: 3c  

$$\text{Fe}_2\text{O}_3 + 6\text{Li}^+ + 6\text{e}^- \rightleftharpoons 2\text{Fe} + 3\text{Li}_2\text{O} \quad (1)$$

The TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> electrode still showed the most competitive rate 3c  
 capability with capacity of 168.3 mAh g<sup>-1</sup> at 1600 mA g<sup>-1</sup>, much 3c  
 higher than the capacity of bare TiO<sub>2</sub> and Fe<sub>2</sub>O<sub>3</sub> electrodes. The 3c  
 coulombic efficiency of the above three electrodes at the condition 3c  
 of cycling and rate performance test is presented in Fig. S9†. The 3c  
 TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> electrode possessed a little bit better coulombic 3c  
 efficiency than that of TiO<sub>2</sub> and Fe<sub>2</sub>O<sub>3</sub> electrodes although all of 3c  
 the electrodes had good efficiency, which is significantly important to 3c  
 the applications of the materials. 3c

88 **Fig. 3.** Electrode performance: (a) CV curves of TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> 88  
 89 electrode; (b) the 1st, 65th and 103rd galvanostatic charge-discharge 89  
 90 profiles of TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> electrode; (c) cycling performance and 90  
 91 coulombic efficiency of TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub>, TiO<sub>2</sub> and Fe<sub>2</sub>O<sub>3</sub> electrodes at 91  
 92 200 mA g<sup>-1</sup>; (d) rate performance and coulombic efficiency of 92  
 93 TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub>, TiO<sub>2</sub> and Fe<sub>2</sub>O<sub>3</sub> electrodes at different current 93  
 94 densities. 94

95 In summary, we have successfully synthesized hierarchical 95  
 96 TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> nanoframework arrays. As a result of the buffering 96  
 97 effect of mesoporous TiO<sub>2</sub> nanosheets and the abundant free space 97  
 98 between Fe<sub>2</sub>O<sub>3</sub> nanorods and mesoporous structures, the hybrid 98  
 99 99

1 TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> electrode shows superior cycling performance and rate  
 2 capability to bare TiO<sub>2</sub> and Fe<sub>2</sub>O<sub>3</sub> electrodes. The synergetic effect of  
 3 the hybrid materials also has great effect on the electrochemical  
 4 properties. Substantially, the introduction of Fe<sub>2</sub>O<sub>3</sub> nanorods plays  
 5 a significant role in advancing the specific capacity of the  
 6 TiO<sub>2</sub>@Fe<sub>2</sub>O<sub>3</sub> electrode and the mesoporous TiO<sub>2</sub> nanosheets as the  
 7 scaffold has the advantage for keeping the excellent cyclability. It is  
 8 expected that the special fabrication strategies mentioned in this  
 9 article will be widely utilized to construct other hybrid  
 10 nanostructures for improving the electrochemical performance of  
 11 low-capacity materials such as Li<sub>4</sub>Ti<sub>5</sub>O<sub>12</sub> and graphite.
