This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard Terms \& Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.

# Asymmetric organocatalytic desymmetrization of 4,4-disubstituted cyclohexadienones at high pressure: a new powerful strategy for the synthesis of highly congested chiral cyclohexenones ${ }^{1, \dagger}$ 

Naomu Miyamae, Naruhisa Watanabe, Maya Moritaka, Keiji Nakano, Yoshiyasu Ichikawa, and ${ }_{5}$ Hiyoshizo Kotsuki*

Received (in $X X X, X X X$ ) Xth $X X X X X X X X X$ 20XX, Accepted Xth $X X X X X X X X X$ 20XX<br>DOI: 10.1039/b000000x

A highly diastereoselective and enantioselective method for the asymmetric desymmetrization of 4,4disubstituted cyclohexadienones by using the Michael addition reaction of malonates under catalysis with
10 the primary amine-thiourea conjugate catalyst and PPY at high pressure was developed.

## Introduction

Asymmetric desymmetrization can provide a powerful and highly expedient strategy for the construction of two or more new chiral stereogenic centers from prochiral compounds in a single-step
15 operation. Accordingly, a variety of methods that use both enzymatic and non-enzymatic processes have been developed that show high to excellent enantioselectivity, and most involve the intrinsic nature of meso-anhydrides, epoxides and diols. ${ }^{2}$ In addition to these precedents, recent efforts have been directed to 20 explore the versatile utility of organocatalytic transformations. ${ }^{3}$ These include, for example, functionalization of meso-diols and anhydrides, ${ }^{4}$ aldol and related reactions, ${ }^{5}$ discrimination of cyclohexadienes, ${ }^{2 \mathrm{f}, 6}$ Baeyer-Villiger oxidation of cyclobutanones, ${ }^{7}$ and others. ${ }^{8}$ Among these, we were particularly
25 interested in devising an efficient method for differentiating between the two double bonds in 4,4-disubstituted cyclohexadienones based on organocatalytic asymmetric Michael addition reactions, since functionalized cyclohexenones or cyclohexanones are important key components in synthetic and 30 natural products chemistry. ${ }^{9}$

Although there have been reports on intramolecular approaches to the desymmetrization of cyclohexadienones, ${ }^{6 \mathrm{~g}, \mathrm{~h}, \mathrm{j}-\mathrm{n}}$ to the best of our knowledge, very little information is available on intermolecular variants. ${ }^{6 p, 10}$ Presumably, this might be the result 35 of severe steric congestion at $\beta$-carbon atoms. Despite this fairly limited accessibility, we thought that the asymmetric discrimination of cyclohexadienones based on an intermolecular Michael addition strategy would be a great challenge for the

synthesis of cyclohexenone derivatives containing up to two stereocenters, in which an all-carbon quaternary stereogenic 50 center was part of the stereoarray. In view of the great advances in the organocatalytic construction of quaternary stereogenic carbon centers, ${ }^{11}$ this should contribute to progress in this field. Herein, we report a highly successful method for realizing this expectation by taking advantage of our recent findings on 55 asymmetric Michael addition reactions using a dual catalyst system composed of the primary amine-thiourea conjugate catalyst $\mathbf{A}$ or $\mathbf{B}$ and 4-pyrrolidinopyridine (PPY) (Figure 1). ${ }^{12}$

## Results and discussion

The starting 4,4-disubstituted cyclohexadienones 1a-f used in this work were prepared by $\alpha$-selenylation followed by oxidative
${ }_{65}$ elimination of the corresponding cyclohexenone precursors, ${ }^{13}$ which were readily accessible from $\alpha, \alpha$ '-disubstituted acetaldehydes and methyl vinyl ketone via Robinson-type annulation. ${ }^{14}$ On the other hand, 4-methyl-4-trichloromethyl-2,2cyclohexadienone ( $\mathbf{1 g}$ ) was prepared from $p$-cresol by the Zincke${ }_{70}$ Suhl reaction, as described in the literature. ${ }^{15}$

First, we examined the asymmetric desymmetrization of 4-methyl-4-phenyl-2,5-cylohexadienone (1a) through the Michael addition reaction of diethyl malonate (2). The results are summarized in Table 1.
75 Under our previously established standard conditions with 10 $\mathrm{mol} \%$ of catalyst $\mathbf{A}$ and $10 \mathrm{~mol} \%$ of PPY at atmospheric pressure, ${ }^{12 \mathrm{a}}$ the desired reaction proceeded sluggishly to afford

${ }^{a}$ Reactions performed at a concentration of 0.2 M in the solvent listed. ${ }^{b}$ Combined yields of isolated products $\mathbf{3 a}$ and $\mathbf{4 a}$. Yields based on the reacted
 $\operatorname{PrOH}=90: 10$, flow rate $1.0 \mathrm{~mL} / \mathrm{min}, \lambda=254 \mathrm{~nm}$ ). ${ }^{e} \mathrm{THF}$ was used as a solvent. ${ }^{f} 0.5 \mathrm{M}$ in the solvent. ${ }^{g}$ By-product 5 was isolated in $43 \%$ yield.
${ }^{h}$ Catalyst $\mathbf{B}$ was used in place of catalyst $\mathbf{A}$.
the desymmetrization products anti-adduct $\mathbf{3 a}$ and syn-adduct $\mathbf{4 a}$ with high diastereo- and enantioselectivity, but in only $11 \%$ yield (entry 1). We applied a high-pressure technique to accelerate this reaction, ${ }^{12 b, 16}$ and observed that the pressure played an essential 5 role in the present system (entry 2 ). Consistent with our previous observations, ${ }^{17}$ when THF was used as a solvent, the reaction progress was completely suppressed, which indicated that a hydrogen-bond interaction between the substrate and the catalyst may be inhibited in this HBD solvent (entry 3). ${ }^{18}$ While an 10 increase in the catalyst loading to $30 \mathrm{~mol} \%$ improved the product yield (entry 4 ), ${ }^{19}$ the use of 3 equiv of 2 resulted in the formation of a large amount of the double-Michael adduct 5 due to the ease of the second-step reaction (entry 5) (Figure 2).

15

5

Fig. 2 By-product 5.

After several experiments, we concluded that this problem could be easily solved by using an excess of $\mathbf{1 a}$, and the products ${ }_{20} \mathbf{3 a}$ and $\mathbf{4 a}$ were obtained in $82 \%$ combined yield with high diastereo- $\mathbf{( 3 a / 4 a}=84: 16)$ and enantioselectivity ( $\mathbf{3 a}, 92 \%$ ee; 4a, $86 \%$ ee) (entry 6 ). In this case we also recognized the critical
factor of pressure and yields decreased at lower pressures (entries $6-8$ ). ${ }^{12 \mathrm{~b}}$ As expected, the use of catalyst B completely reversed 25 this desymmetrization dictation (entry 9).

With our optimized reaction conditions in hand, we then explored the general scope of the reaction, and the results are summarized in Table $2 .{ }^{20}$ All reactions were performed in toluene at 0.8 GPa and rt for 2 days in the presence of $30 \mathrm{~mol} \%$ of the ${ }_{30}$ respective catalyst $\mathbf{A}$ and PPY. Various 4-alkyl-4-aryldisubstituted cyclohexadienones 1b-f reacted smoothly with $\mathbf{2}$ to give the products in good yields (up to $99 \%$ ) and with high diastereo- (up to $93: 7$ ) and enantioselectivity (up to $93 \%$ ee for 3 and $99 \%$ ee for 4 ). When the size of the 4 -alkyl group was 35 increased from Me to Et (compare 3a with 3b), the diastereoselectivity significantly decreased, while the enantioselectivity remained roughly the same. Unexpectedly, cyclohexadienone 1 g could react only very slowly even with 1 equiv of $\mathbf{2}$ at 0.8 GPa for 4 days and the product $\mathbf{3 g}$ was obtained 40 as an almost single diastereomer in $10 \%$ yield with $33 \%$ ee.

The absolute configurations of the products $\mathbf{3 a}$ and $\mathbf{4 a}$ were determined unambiguously by conversion to the corresponding cyclohexanone derivatives 7 and $\mathbf{1 0}$, and comparison of their optical rotations with those of the authentic samples prepared ${ }_{45}$ independently from optically pure $(R)$-cyclohexenone $\mathbf{8}^{14}$ (Scheme 1). Thus, catalytic hydrogenation of 3a in EtOH as a solvent at rt in the presence of a catalytic amount of $\mathrm{Pd} / \mathrm{C}$ afforded 7, $[\alpha]^{27}{ }_{\mathrm{D}}+5.4$ ( $c=0.49$, EtOH, $92 \%$ ee), in $36 \%$ yield $^{21}$ without a loss of diastereomeric and enantiomeric excess. On the

other hand, the authentic sample of $(3 S, 4 R)-9,[\alpha]^{26}-5.8(c=$ $1.0, \mathrm{EtOH}, 97 \%$ ee), was prepared from 8 and 2 in $77 \%$ yield with high anti-selectivity (syn/anti $=7$ : 93) via the diastereoselective Michael addition reaction using catalyst B at atmospheric pressure and rt for 2.5 days. The results of optical rotation revealed that $\mathbf{7}$ and $\mathbf{9}$ are enantiomers of each other, and hence 7 has a $(3 R, 4 S)$-configuration for the all-carbon substituted quaternary stereogenic center and the adjacent tertiary stereogenic center, and therefore also for the corresponding moieties in 3a. ${ }_{10}$ In a similar manner, the absolute configuration of $\mathbf{4 a}$ was determined to be $(3 R, 4 R)$ after it was reduced to $\mathbf{1 0}$; this compound was in good agreement with $(3 R, 4 R)-\mathbf{1 1}$ derived from $(R)-\mathbf{8}$ with the assistance of catalyst $\mathbf{A}$. The latter reaction proceeded fairly slowly due to steric congestion at the C3 ${ }_{15}$ position, but with good syn-selectivity (syn/anti $=86: 14$ ) as a result of so-called catalyst control. Meanwhile, the relative stereochemistry of syn- and anti-adducts, i.e., $(3 S, 4 R)-9$ and ( $3 R, 4 R$ )-11, was confirmed by NOESY experiments (Figure 3). Thus, $(3 S, 4 R)-9$ revealed an NOE interaction between the C4 20 methyl and the malonate proton, indicating that a phenyl ring has a favorable axial position. ${ }^{22}$ On the other hand, the interaction between the C 4 methyl and the C 3 methine in $(3 R, 4 R)-\mathbf{1 1}$ reflected the existence of a severe steric repulsion between the equatorial phenyl ring and the axial malonate substituent.
25

Fig. 3 NOESY experiments of $(3 S, 4 R)-\mathbf{9}$ and ( $3 R, 4 R$ )-11 (500 $\mathrm{MHz}, \mathrm{CDCl}_{3}$ ). Characteristic correlations are shown. Important vicinal coupling constants are indicated by dashed arrows.
${ }^{30}$ Based on the experimental results described above and our recent studies, we propose a mechanism to account for the present high level of asymmetric desymmetrization of cyclohexadienones (Figure 4). ${ }^{12,16}$ First, the dual catalyst system composed of catalyst $\mathbf{A}$ and PPY can activate both $\mathbf{2}$ as a Michael ${ }_{35}$ donor via double hydrogen bonding with a thiourea part of catalyst $\mathbf{A}$ and $\mathbf{1 a}$ as a Michael acceptor by anchoring to form the ketiminium ion intermediate with a free amine part of catalyst $\mathbf{A}$ (I). After proton abstraction by PPY, the resulting malonate anion then attacks one of the two enantiotopic double bonds from the ${ }_{40}$ less-hindered side opposite a rather bulky phenyl ring as in an intramolecular fashion (II). As a result of the main control from the cyclohexanediamine chiral motif of catalyst $\mathbf{A}$, high discrimination would be enforced to give the desired chiral
adduct (III), 3a after hydrolysis, which is consistent with the ${ }_{45}$ experimental results.

Fig. 4 Plausible mechanism.

## Conclusions

${ }_{50}$ In conclusion, we have developed a highly diastereoselective and enantioselective method for the asymmetric desymmetrization of 4,4-disubstituted cyclohexadienones by using the Michael addition reaction of malonates under catalysis with the primary amine-thiourea conjugate catalyst $\mathbf{A}$ or $\mathbf{B}$ and PPY at high ${ }_{55}$ pressure. This method is particularly useful for constructing highly functionalized cyclohexenones containing a quaternary carbon stereogenic center and two contiguous stereocenters in only one step. Further studies on the application of this method to natural product synthesis are now in progress in our laboratory.

## Experimental section

Typical procedure for the asymmetric desymmetrization of 1a (Table 1, entry 6). A mixture of $\mathbf{1 a}(166 \mathrm{mg}, 0.9 \mathrm{mmol})$ and diethyl malonate ( $\mathbf{2}, 48 \mathrm{mg}, 0.3 \mathrm{mmol}$ ) in the presence of ${ }_{65}$ catalyst A ( $34.7 \mathrm{mg}, 30 \mathrm{~mol} \%$ ) and PPY ( $13.3 \mathrm{mg}, 30 \mathrm{~mol} \%$ ) in toluene ( 1.4 mL ) was placed in a Teflon reaction vessel and the mixture was allowed to react at 0.8 GPa and rt for 2 days. After the pressure was released, the mixture was concd and purified by column chromatography on alumina (eluted with hexane-AcOEt) 70 to give $\mathbf{3 a}(71.4 \mathrm{mg}, 69 \%)$ and $\mathbf{4 a}(13.4 \mathrm{mg}, 13 \%)$ along with the recovered $\mathbf{1 a}(103 \mathrm{mg})$.

9516 . We believe that high pressure can accelerate both the catalystsubstrate interactions and $\mathrm{C}-\mathrm{C}$ bond-forming reactions. For a review on organocatalytic reactions at high pressure, see: P. Kwiatkowski, K. Dudzinski and D. Lyzwa, In Comprehensive Eantioselective Organocatalysis, P. I. Dalko, Ed., Wiley-VCH, Weinheim, 2013; Volume 2, Chapter 21, pp 581-615.

105 19. We did not check the use of $20 \mathrm{~mol} \%$ of catalyst $\mathbf{A}$.
20. Although we did not check other carbon nucleophiles, the process should be also applicable to acetylacetone and related compounds. See Ref. 12.
21. The low yield in this step is due to the formation of complex byproducts.
