This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. This Accepted Manuscript will be replaced by the edited, formatted and paginated article as soon as this is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
COMMUNICATION

Water-Assisted Low Temperature Plasma Ionization Source for Sensitive Detection of Explosives

Wendong Chen, Keyong Hou, Lei Hua, Xingchuang Xiong and Haiyang Li

Received (in XXX, XXX) Xth XXXXXXXXX 20XX, Accepted Xth XXXXXXXXX 20XX
DOI: 10.1039/b000000x

A water-assisted low temperature plasma (WALTP) ionization source based on a quartz T shaped tube was developed for a miniature rectilinear ion trap mass spectrometer to sensitively detect explosives at low picogram level. By introducing wet air into the plasma stream through the side tube, the explosives responses and repeatability were improved, and the mass spectra were simplified.

Sensitive detection of explosives is an important topic involving fields of service services, forensic investigation, and environmental analysis. In most practical explosives analysis cases, the sensitivity and repeatability are extremely essential. Various techniques have been developed for explosives detection, such as Raman spectroscopy, ion mobility spectrometry, and mass spectrometry (MS). Among these methods, MS has been regarded as an effective technique with the features of high sensitivity, high specificity, and rapid analysis speed; furthermore, the appearance of miniature instruments like rectilinear ion trap mass spectrometer (RIT-MS) equipped with discontinuous atmospheric pressure interface (DAPI) and ambient desorption/ionization (ADI) sources expands the applications of MS to the field of on-site analysis.

ADI sources for MS are able to ionize the analyte without sample pretreatment, which have enabled the rapid and sensitive detection of explosives. Up to now, more than thirty kinds of ADI techniques have been developed, e.g., desorption electrospray ionization (DESI), direct analysis in real time (DART), and low temperature plasma (LTP). The LTP has been successfully applied to detect organic and inorganic explosives, including trinitrotoluene (TNT), hexahydro-1,3,5-trinitro-1,3,5-triazine (HMX), pentaerythritol tetranitrate (PETN), and black powder. By merging discharge gas with trifluoroacetic anhydride in the open ambient might harm the operators of the apparatus, which limited their application.

Herein, a safe, environment-friendly, and novelty-constructed water-assisted low temperature plasma (WALTP) ionization source was developed to improve the sensitivity and simplify the mass spectrum for explosives detection, on the basis of no corrosion for electrodes. The limits of detection (LODs) and repeatability were evaluated, and a mixture of explosives was measured to demonstrate the capability of this ionization source for the analysis of complex explosive samples.

In this study, explosives deposited on the polytetrafluoroethylene (PTFE) swab were heated by a halogen lamp; the thermally desorbed sample molecules were then ionized via a WALTP torch and analyzed by a home-made miniature RIT-MS, as shown in Fig. 1. The WALTP utilized dielectric barrier discharge (DBD) to create nonequilibrium plasma with temperature of about 30 °C. The WALTP torch, with total length of 150 mm, was fabricated by a quartz T shaped tube (6 mm o.d. and 4 mm i.d.). The distances from the side tube to the end of WALTP torch and the overlap of discharge electrodes (the position of discharge region) were both 15 mm. A stainless steel cylinder (6.3 mm o.d. and 6.1 mm i.d.) set outside of the tube and a stainless steel rod (1.57 mm o.d.) centered axially were employed as the high voltage (HV) electrode and the internal electrode, respectively. A PVM500 Plasma Resonant Driver (Information Unlimited, New Hampshire, USA) provided an alternating voltage, 1.6 KVp-p at a frequency of 25 KHz, to the HV electrode while the internal electrode was grounded, generating the dielectric barrier discharge. Helium was used as the discharge gas, with a flow rate of 150 mL min⁻¹ for RDX and PETN detection, while that of 100 mL min⁻¹ for 2,4,6-trinitrophenylmethylnitramine (tetryl). Instead of passing through the discharge electrodes, the wet air with a flow rate of 25 mL min⁻¹ was introduced into the plasma stream via a side tube, avoiding the corrosion of discharge electrodes. The wet air was prepared by bubbling through purified water, and its relative humidity was 100% measured by a dew point sensor (DP300, CS Instrument GMH). The dimension of miniature RIT-MS was 38×34×26 cm and its total weight was 20 kg. The mass range of RIT-MS was m/z 70-600. The detail analytical procedure and the configuration of RIT-MS were described previously.
Fig. 1 Schematic of the explosives detection platform consisting of a water-assisted low temperature plasma (WALTP) torch, a halogen lamp, and a rectilinear ion trap mass spectrometer.

Three samples, 0.5 ng RDX, 0.5 ng PETN, and 0.5 ng tetryl, were tested to estimate the analytical performances of WALTP for the explosives analysis. As a comparison, these explosives were also measured when the side tube of WALTP was sealed (equal to the conventional LTP)\(^6\). As illustrated in Fig. 2, the mass spectra of RDX and PETN are characterized by nitro adducts of \([\text{M}+\text{NO}_2]^-\) and \([\text{M}+\text{NO}_3]^-\), while the mass spectrum of tetryl is characterized by \([\text{Tetryl}+\text{NO}_3]^-\); \([\text{HNO}_3+\text{NO}_3]^-\) is the dominant reactant ion in the WALTP. From Fig. 2, it is clear that the use of WALTP brings an enhancement for \([\text{M}+\text{NO}_3]^-\) intensities, about 3-fold (RDX), 2-fold (PETN), and 2-fold (tetryl) respectively as high as those obtained by the conventional LTP. Moreover, the mass spectra obtained by the WALTP are much cleaner. The relative intensities for \([\text{RDX}+\text{NO}_2]^-\) and \([\text{PETN}+\text{NO}_2]^-\) are decreased, and the intensities of fragment ions for tetryl\(^6\) are reduced to about one-fifth \((m/z\) 181\)), one-fifths \((m/z\) 210\)), one-eighth \((m/z\) 241\)), and one-fourth \((m/z\) 257\)) respectively of those obtained by the conventional LTP. It has been reported that the ionization of 2,4-dinitrotoluene would form the deprotonated ion \((m/z\) 181\)) by the conventional LTP, while that of TNT would form the fragment ion with \(m/z\) of 210.\(^6\) Therefore, the mass peaks for fragment ions of tetryl \((m/z\) of 181 and 210\)) would overlap with those for the deprotonated ion of 2,4-dinitrotoluene and fragment ion of TNT. Encouragingly, the reduction of fragment ions for tetryl by the WALTP would avoid the serious overlap of mass peaks for different explosives and simplify the mass spectrum, which is a benefit for the qualitative and quantitative analysis of mixed explosives.

The detail mechanism for the reduction of fragment ions using the WALTP torch needs further study, so only a preliminary deduction is given below. First, the increased \([\text{HNO}_3+\text{NO}_3]^-\) ions in the WALTP ionization source (shown in Fig. 3) were easier to react with explosives to form stable \([\text{M}+\text{NO}_3]^-\) ions than the reactant ions \(\text{NO}_3^-\), as the extra reaction heat could be taken away by neutral molecules \(\text{HNO}_3\), which would avoid their further fragmentation. Second, the introduction of \(\text{H}_2\text{O}\) molecules might decrease the amount of metastable species in the plasma, which might avoid the dissociative ionization of explosives.

To investigate the reasons for the response improvement of explosives by the WALTP, the mass spectra of reactant ions for the WALTP and conventional LTP were recorded, respectively. Since the low mass cut-off of the RIT-MS was \(m/z\) 70, this experiment was implemented by an atmospheric pressure time-of-flight mass spectrometer. As demonstrated in Fig. 3, the intensity of \([\text{HNO}_3+\text{NO}_3]^-\) for the WALTP is about 3 times as high as that for the conventional LTP, while the intensities of \(\text{NO}_3^-\) are almost equal for both ionization sources, and the intensity of \(\text{NO}_2^-\) is decreased in the WALTP. Apparently, the enhancement factor of \([\text{HNO}_3+\text{NO}_3]^-\) intensity is approximately corresponding to that of \([\text{M}+\text{NO}_3]^-\) intensity for the three explosives. Hence, we deduce that the explosive product ions \([\text{M}+\text{NO}_3]^-\) were mainly produced by the reaction of their molecules \(\text{M}\) with \([\text{HNO}_3+\text{NO}_3]^-\), and the probable reason for the improvement of \([\text{M}+\text{NO}_3]^-\) intensities was that the amount of \([\text{HNO}_3+\text{NO}_3]^-\) was significantly enhanced after introducing wet air into the WALTP.
As depicted in Fig. 4, it is notable that comparing to those 
acquired by the conventional LTP, the intensities of [M+NO₃⁻]
for these three explosives are improved. Furthermore, by 
adopting the WALTP, only one prominent peak [M+NO₃⁻] for 
each of the explosives can be obtained, which greatly simplifies 
the mass spectrum.

In summary, a simple, safe, and environment-friendly WALTP 
torch has been developed and tested for sensitive detection of 
explosives. Its special configuration basing on a quartz T shaped 
torch allows wet air to be introduced into the plasma stream via a 
side tube, which protects the discharge electrodes from corrosion 
by the oxidizing gas. With the WALTP, the sensitivity and 
repeatability for the detection of explosives are interestingly 
improved; and LODs at the low picogram level have been 
achieved for RDX, PETN, and tetryl (e.g., 5 pg for RDX). The 
improvement of [M+NO₃⁻] intensities for the three selected 
explosives is probably attributed to the increase of reactant ion 
[HNO₃+NO₃]⁻. Finally, the mass spectrum of a mixed explosive 
sample obtained by the WALTP is characteristic and very clean, 
which is a benefit for their qualitative and quantitative analysis.
