The environmentally friendly synthesis of nanomaterials using green chemistry has attracted tremendous attention in recent years due to its easy handling, low cost, and biocompatibility. Here we demonstrate a facile and efficient route for the synthesis of highly reduced graphene oxide (PE-HRG) by green reduction of graphene oxide (GRO) using a *Pulicaria glutinosa* plant extract (PE). The phytochemicals present in the *P. glutinosa* extract are not only responsible for the reduction of GRO, they also functionalize the surface of the PE-HRG nanosheets and stabilize them in various solvents, thereby limiting the use of any other external and harmful chemical reductants and surfactants. The effect of PE on the dispersibility of PE-HRG in various solvents was investigated by preparing the PE-HRG with different amounts of PE, and the dispersibility of PE-HRG was compared with that of chemically reduced graphene oxide (CRG). The reduction of GRO was confirmed by ultraviolet–visible (UV-Vis), Fourier-transform infrared (FT-IR), Raman and X-ray photoelectron (XPS) spectroscopy, thermogravimetric analysis (TGA), X-ray powder diffraction (XRD) and transmission electron microscopy (TEM).

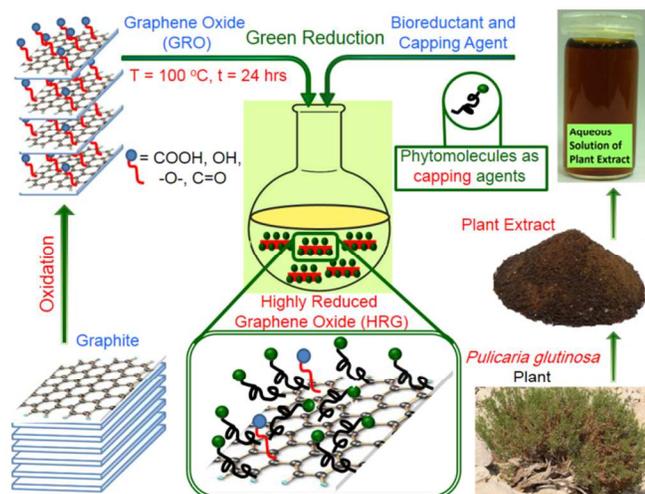

### Introduction

Graphene based materials have been a target for the vigilant eyes of attraction for nanotechnologists, owing to their exceptionally high crystal and electronic qualities. It has emerged as a promising new nanomaterial for a variety of exciting applications despite its short history.<sup>1,2</sup> Due to the stable 2D structure and superior thermal, mechanical and electrical properties,<sup>3-5</sup> graphene is widely used in various fields, including electronics,<sup>6</sup> energy storage,<sup>7</sup> catalysis,<sup>8-11</sup> biosensors<sup>12</sup> and biomedicine.<sup>13,14</sup> Although, graphene has been used as a theoretical model to describe the electronic structure of graphitic species for over half a century,<sup>15</sup> researchers have had difficulty in obtaining experimentally relevant amounts of this material until the very recent development of mechanical<sup>16</sup> and chemical synthetic methods.<sup>17-19</sup> Tremendous attention has been paid to the low-cost bulk production of graphene and graphene based materials.<sup>20-22</sup> Several methods have been reported. Chemical exfoliation strategies, have been applied extensively.<sup>23-25</sup> Sequential oxidation-reduction of graphite and chemical exfoliation of graphite followed by chemical reduction typically yield flakes of graphene.<sup>26,27</sup> These techniques yield bulk amounts of graphene like sheets best described as highly reduced graphene oxide (HRG).<sup>28,29</sup> It is not defect free, but highly

processable and can be merged with a variety of materials, including various graphene-based bio- and nanocomposites.<sup>30-32</sup>

The reduction of graphite oxide (GO) or graphene oxide (GRO) to HRG can be performed by chemical,<sup>33-35</sup> thermal,<sup>36</sup> electrochemical<sup>37</sup> and photochemical methods.<sup>38,39</sup> The chemical reduction of GRO is considered most promising for a large scale preparation of HRG at low cost.<sup>40</sup> So far, strongly reducing agents such as hydrazine, sodium borohydride, hydroquinone, hydrohalic acid or formamidesulfonic acid have been applied for the reduction of GRO to HRG.<sup>41-43</sup> However, these chemical reductants, in particular the commonly applied hydrazine, are hazardous and harmful to both human life and environment. Moreover, the chemical methods may result in “doping” with other elements (nitrogen in case of hydrazine) which leads to an altering of the electronic properties of graphene.<sup>44</sup> Besides, there is a strong tendency of irreversible agglomeration and precipitation of chemically reduced GRO sheets due to the  $\pi$ - $\pi$  stacking, which is usually prevented by the addition of chemical stabilizers such as porphyrins, pyrenebutyric acid, or poly(oxyalkylene) amines (POA).<sup>45,46</sup> Therefore efforts have been directed towards the development of protocols which make use of eco-friendly reducing agents for the production and stabilization of HRG.<sup>47</sup> So far, a couple

of natural products including, gallic acid, L-lysine, melatonin, L-ascorbic acid, green tea, and wild carrot roots have been explored for the preparation of HRG.<sup>48-53</sup> Recently, the trend of applying plant extracts as both reducing and stabilizing agents during the preparation of nanomaterials, have attracted considerable attention.<sup>54,55</sup> The plant extracts (PE) are relatively easy to handle, readily available, low cost, and they have been greatly exploited due to their biocompatibility in the field of nanotechnology.<sup>56,57</sup> Although metal nanoparticles have been synthesized using plant extracts as bioreductants their reducing abilities have been rarely tested for the reduction of GO.<sup>58-60</sup>

**Scheme 1.** Green reduction of graphene oxide (GO) using an aqueous extract of the *P. glutinosa* plant.

In this study, we report a facile and environmentally friendly approach for the preparation of highly reduced graphene oxide (HRG) sheets by using an extract from *P. glutinosa* (PE), which has been collected from the local fields in Saudi Arabia (Scheme 1). The PE not only acts as a bioreductant but also functionalize the surface of the PE-HRG sheets.<sup>60</sup> The as-prepared PE-HRG was characterized using various microscopic and analytical techniques including, X-ray powder diffraction (XRD), X-ray photoelectron spectroscopy (XPS), Fourier-transform infrared spectroscopy (FT-IR), Raman spectroscopy, ultraviolet-visible absorption (UV-Vis) spectroscopy.

## Experimental Section

**Materials and Methods.** Graphite powder (99.999%, -200 mesh) was purchased from Alfa Aesar. Concentrated sulfuric acid ( $\text{H}_2\text{SO}_4$  98%), potassium permanganate ( $\text{KMnO}_4$  99%), sodium nitrate ( $\text{NaNO}_3$ , 99%) and hydrogen peroxide ( $\text{H}_2\text{O}_2$ , 30 wt%) and all organic solvents were obtained from Aldrich chemicals and used without further purification.

### Synthesis

The whole plant of wild growing *P. glutinosa* was collected from the hilly area of Al-Hair in central Saudi Arabia during March 2011. The identity of the plant material was confirmed by a plant taxonomist from the Herbarium Division of the Col-

lege of Science, King Saud University, Riyadh, Kingdom of Saudi Arabia. A voucher specimen was deposited in our laboratory as well as in the Herbarium Division of King Saud University with the voucher specimen number KSU-21598. The details of the preparation of plant extract were given in our previous study.<sup>60</sup> The solution of the plant extract, which was used for the reduction of GRO, was prepared with 0.1 gram of plant extract in 1 mL of solvent. The chemically reduced graphene oxide (CRG) used during the dispersion studies, was obtained by the reduction of GRO using hydrazine hydrate.<sup>61</sup>

**Preparation of Graphite Oxide (GO).** Graphite oxide (GO) was synthesized from graphite powder by a modified Hummers method.<sup>62,63</sup> Initially, 2 g of natural graphite and 1.75 g of  $\text{NaNO}_3$  (purity 99%) were taken in a three-neck flask, to which 150 mL of  $\text{H}_2\text{SO}_4$  (98%) were added slowly. The mixture was allowed to stir for 2 h under ice-water bath environment, after 2 h, 9 g of  $\text{KMnO}_4$  (99%) were slowly added under constant stirring over a period of 2 h. The remaining mixture was allowed to react for five days at room temperature. Thereafter, 200 mL of 5 wt%  $\text{H}_2\text{SO}_4$  aqueous solution was added over a period of 1 h and stirred for another 2 h. Afterwards, 6 g of 30 wt%  $\text{H}_2\text{O}_2$  aqueous solution were added, and the mixture was stirred for another 2 h. The solution was washed several times with an aqueous solution of 3 wt%  $\text{H}_2\text{SO}_4$  and 0.5 wt%  $\text{H}_2\text{O}_2$ . This process was repeated three times with deionized water (DI). The resulting mixture was dispersed in DI water and centrifuged for 2 h at 9000 rpm. The dispersion was washed 20 times with DI water until a homogeneous brown-black dispersion was obtained.

**Preparation of Highly Reduced Graphene Oxide (PE-HRG).** Graphite oxide, GO (200 mg) was first dispersed in 40 mL of distilled water and sonicated for 30 min to obtain graphene oxide (GRO) sheets. The resultant suspension was heated to 100 °C. Subsequently 10 mL of an aqueous solution of plant extract (0.1 gram/mL) was added into the suspension, which was then allowed to stir for 24 h at 98 °C. Subsequently the highly reduced graphene oxide (PE-HRG-1) was collected by filtration as a black powder, washed with distilled water several times to remove the excessive plant extract residue and redistributed into water for sonication. This suspension was centrifuged at 4000 rpm for another 30 min. The final product was collected by vacuum filtration and dried in vacuum.

### Characterization

**UV/Vis spectroscopy.** A Perkin Elmer lambda 35 (USA) UV-Vis spectrophotometer was used for the optical measurements. The analysis was performed in quartz cuvettes, using DI water as a reference solvent. The stock solutions of HRG and GRO for the UV measurements were prepared by dispersing 5 mg of sample in 10 mL of DI water and sonicating for 30 min. The UV samples of GRO and PE-HRG were prepared by diluting 1 mL of stock solution in 9 mL of water.

**X-ray diffraction.** XRD diffractograms were collected on a Altima IV [Make: Rigaku, Japan] X-ray powder diffractometer using  $\text{Cu K}\alpha$  radiation ( $\lambda=1.5418 \text{ \AA}$ ).

**Transmission electron microscopy.** Transmission electron microscopy (TEM) was performed on a JEOL JEM 1101 (USA) transmission electron microscope. The samples for TEM

were prepared by placing a drop of primary sample on a holy carbon copper grid and drying for 6 h at 80 °C in an oven.

**Fourier transforms infrared spectrometer.** FT-IR spectra were measured on a Perkin- Elmer 1000 (USA) Fourier transforms infrared spectrometer. In order to remove any free biomass residue or unbound extract to the surfaces of PE-HRG sheets, the PE-HRG nanosheets were repeatedly washed with distilled water; subsequently the product was centrifuged at 9000 rpm for 30 min and dried. The purified PE-HRG nanosheets were mixed with KBr powder and pressed into a pellet for measurement. Background correction was made using a reference blank KBr pellet.

**X-ray photoelectron spectroscopy:** XPS spectra were measured on a PHI 5600 Multi-Technique XPS (Physical Electronics, Lake Drive East, Chanhassen, MN) using monochromatized Al K $\alpha$  at 1486.6 eV. Peak fitting was performed using CASA XPS Version 2.3.14 software.

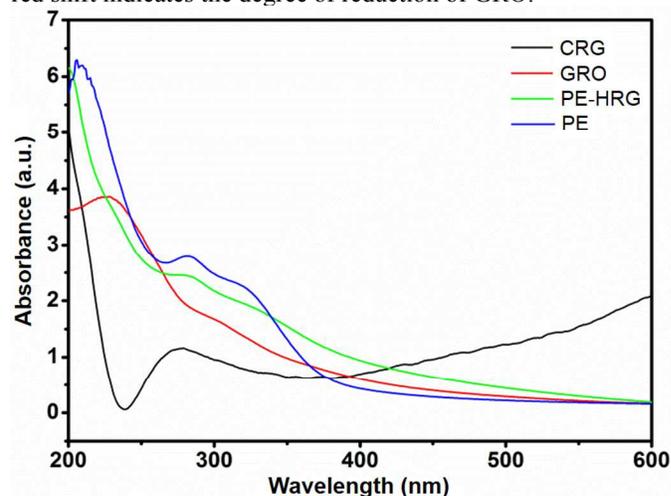

**Atomic Force Microscopy (AFM).** Samples for AFM investigations were prepared by drop casting. One drop of sample solution was deposited from a 100  $\mu$ L syringe on a freshly cleaved mica surface. Subsequently, the mica sheet was transferred into a high vacuum chamber and dried overnight. All AFM images were recorded with a commercial AFM (Multimode, Nanoscope IIIa controller, Veeco, California, USA) in tapping mode. This instrument was equipped with a piezoelectric scanner allowing a maximum x,y-scan size of 17  $\mu$ m and a maximum z-extension of 3.9  $\mu$ m. Silicon cantilevers (OMCL-AC240TS (Olympus), 240  $\mu$ m long, 30  $\mu$ m wide, 2.8  $\mu$ m thick) with an integrated tip, a nominal spring constant of 2 N/m and 42 N/m, a tip radius <10 nm and nominal resonance frequencies of 150 kHz and 450 kHz were plasma cleaned prior to use.

## Results and Discussion

*P. glutinosa* plant extract was used for the synthesis of highly reduced graphene oxide (PE-HRG) as illustrated in Scheme 1. Briefly, plant extract was added to GRO and the contents of the flasks were refluxed for 24 h. The color of GRO changed gradually from dark brown to black after addition of plant extract (PE), indicating the reduction of GRO. Under a similar set of conditions without addition of PE, no color change was observed even after 72 hours. The PE-HRG was also compared with chemically reduced graphene oxide (CRG), which was obtained via hydrazine reduction of GRO. To evaluate the effect of the PE concentration on the reduction efficiency of GRO and the surface functionalization of PE-HRG to improve the solubility, three different PE-HRG samples were prepared using 10 ml (PE-HRG-1), 20 ml (PE-HRG-2) and 50 ml (PE-HRG-3) of plant extract with a concentration of 0.1g/mL while keeping the amount of GRO constant.

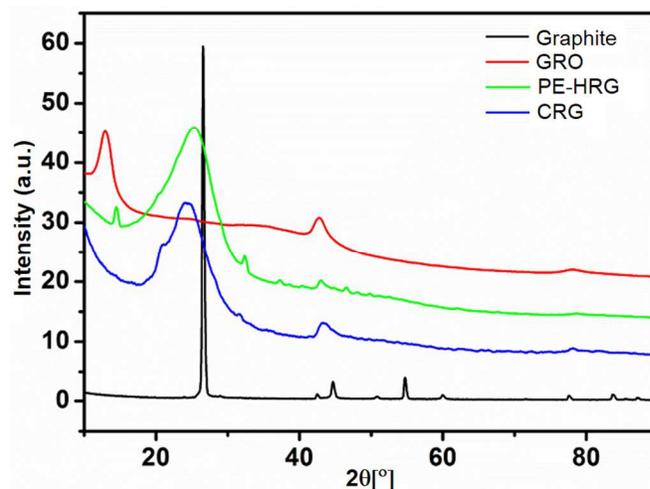

The reduction of GRO was initially monitored by UV-Vis spectroscopy as shown in Fig. 1. The GRO shows two characteristic absorption bands at  $\sim$ 230 nm and 301 nm (Fig. 1 red line). Upon chemical reduction (CRG) of GRO with hydrazine both bands vanished, and a new absorption band at  $\sim$ 271 nm appeared (Fig. 1 black line), which also shows the reduction of GRO.<sup>54</sup> Notably, in the case of PE mediated reduction of GRO i.e. PE-HRG the absorption peak of the GRO at 230 nm was red shifted to 280 nm (Fig. 1 green line). This shift is considerably

higher than that of chemically reduced GRO (CRG) which exhibited the absorption maximum at 271 nm. This shows a higher degree of reduction in the case of using PE because the red shift indicates the degree of reduction of GRO.<sup>48</sup>

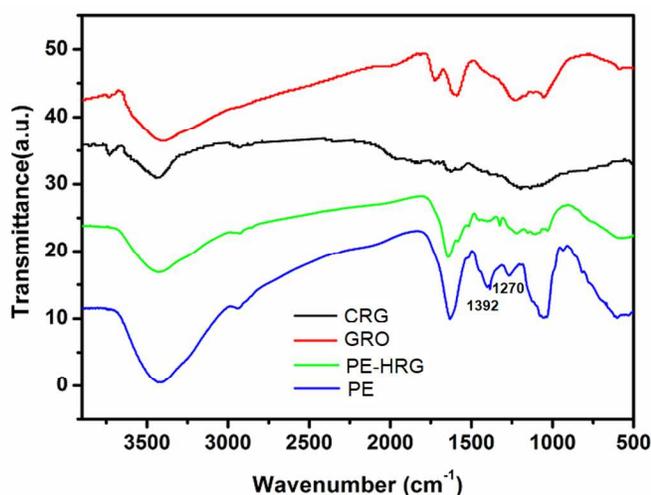

**Fig. 1.** UV-Vis absorption spectra of graphene oxide (GRO, red line), highly reduced graphene oxide (PE-HRG, green line) reduced with PE, chemically reduced graphene oxide (CRG, black line) and pure plant extract (PE, blue line). Although the concentration of CRG was the same as that of PE-HRG, it exhibits a much lower absorption coefficient due to its poor dispersibility in water.

Moreover, the plant extract mediated reduction (PE-HRG) showed an extra absorption peak at  $\sim$ 323 nm, (Fig. 1 green line), which is due to the phytomolecules of the PE bound to the PE-HRG surfaces as confirmed by comparing the absorption spectra of PE-HRG and pure PE (Fig. 1 blue line). The intensity of the absorption band at  $\sim$ 323 nm in PE-HRG, (which is the characteristic peak of the PE) increased with increasing concentration of the PE during the reduction of GRO. This clearly indicates that the PE not only reduces GRO, but that the residual phytomolecules of PE functionalize the surface of PE-HRG.

**Fig. 2.** XRD diffractograms of graphite, graphene oxide (GRO), PE mediated highly reduced graphene oxide (PE-HRG) and chemically reduced graphene oxide (CRG).

Pristine graphite, GRO, CRG and PE-HRG nanosheets were further characterized by XRD (Fig. 2). The pristine graphite exhibits a very intense and narrow reflection at  $2\theta = 26.4^\circ$  corresponding to the (002) planes of the graphene layers with a *d* spacing of 0.34 nm.<sup>18</sup> However, during the course of the oxidation, various oxygen containing functional groups were incorporated between the carbon nanosheets, leading to the shift of the GRO reflection to a lower Bragg angle ( $2\theta = 10.9^\circ$ ). Apart from the functional groups a large number of water molecules were intercalated between the layers. As a result, the *d* spacing of GRO increased to 0.79 nm, which is almost twice as large as the *d* spacing of pristine graphite (0.34 nm). However, the reflection of GRO at  $10.9^\circ$  disappeared in HRG after the reduction which suggests that the oxygen-containing functional groups were essentially removed. Besides, a broad reflection centered at  $2\theta = 22.4^\circ$  in the diffraction pattern of PE-HRG, indicates the formation of graphene nanosheets with a thickness of a few layers.<sup>23</sup>

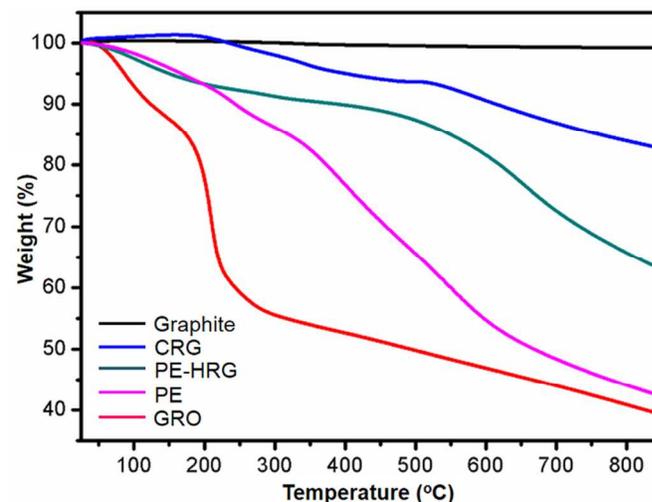

**Fig. 3:** FT-IR spectra of graphene oxide (GRO), PE-mediated highly reduced graphene oxide (PE-HRG), and chemically reduced graphene oxide (CRG) prepared with hydrazine hydrate and plant extract (PE).

The FT-IR spectrum of GRO contains several bands which indicates the presence of oxygen-containing moieties like carbonyl, carboxylic, epoxy and hydroxyl groups (Fig. 3).<sup>26,43</sup> The reduced intensities of the bands (at 1985, 1727, 1605, 1234 and 1047  $\text{cm}^{-1}$ ) associated with the oxygen containing functional groups show the reduction of the GRO, i.e. the number of oxygen-containing functional groups decreased significantly after reduction (Fig. 3).

Still, some of the bands observed in the spectrum of PE-HRG could be due to the presence of phytomolecules bound after in situ functionalization. This was confirmed by a comparison of the IR spectra of PE-HRG and the pure plant extract (Fig. 3). Most of the absorption bands due to PE also appear in the FT-IR spectrum of PE-HRG. This strongly suggests that the phytomolecules of PE act not only as bioreductants, but also as stabilizers by adsorption to the HRG sheets. Notably, the missing absorption bands at 1392  $\text{cm}^{-1}$  and 1270  $\text{cm}^{-1}$  of the phenolic OH groups in the FT-IR spectrum of PE-HRG (present in the

spectrum of PE due to phenolic OH) suggest a possible reduction of GRO is carried out by phenolic OH groups.

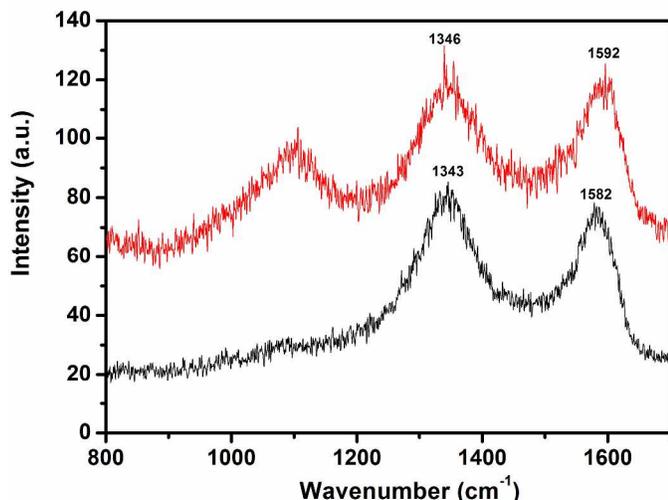

**Fig. 4:** TGA traces of pure graphite, plant extract (PE), graphene oxide (GRO), chemically reduced graphene oxide (CRG) and highly reduced graphene oxide (PE-HRG) using plant extract.

The reduction of GRO was monitored by thermal analysis. The TGA traces of pure graphite, pure PE, GRO, PE-HRG- and CRG are shown in Fig. 4. Graphite did not show any weight loss (Fig. 4 black line), whereas for GRO several degradation steps were observed (Fig. 4 red line). Initially, ~15% weight loss at about 110  $^\circ\text{C}$ , may be assigned to the loss of adsorbed water, followed by another steep step (weight loss ~25%) at ~200  $^\circ\text{C}$ , which was assigned to the thermal elimination of labile oxygen-containing functional groups (hydroxyl or epoxy). A gradual weight loss of ~20% was observed in the temperature range from 200-800  $^\circ\text{C}$ . The total residual weight of GRO obtained at 800  $^\circ\text{C}$  was around 40%.<sup>38,48</sup>

CRG exhibited no weight loss up to 250  $^\circ\text{C}$ . However, in the temperature range of 250-800  $^\circ\text{C}$  CRG exhibited a weight loss of ~15% (Fig. 4 blue line). The PE-HRG showed less weight loss around 200  $^\circ\text{C}$  compared to GRO, but a total weight loss of ~30% between 500  $^\circ\text{C}$  - 800  $^\circ\text{C}$ , which could be due to PE bound to the surface of PE-HRG (Fig. 4 green line). This was confirmed by the TGA trace of the pure PE (Fig. 4 pink line), which also showed the same trend, presumably due to the PE extract bound to the surfaces. The residual weight obtained after annealing CRG and PE-HRG was about 85% and 70% at 800  $^\circ\text{C}$ , respectively (Fig. 4).<sup>50</sup> The higher weight loss for PE-HRG (30%) compared to CRG (15%) can be assigned to surface-bound phytomolecules.

Raman spectroscopy was used to characterize GRO and PE-HRG.<sup>41</sup> The Raman spectra of graphene contain two main features, band G and band D, which occur at 1575  $\text{cm}^{-1}$  and 1350  $\text{cm}^{-1}$ , respectively.<sup>50</sup> The G and the D bands of GO are shifted and appear at 1592 and 1346  $\text{cm}^{-1}$  (Fig. 5 red line), respectively, due to the destruction of  $\text{sp}^2$  character and formation of defects in the sheets caused by the extensive oxidation. After the reduction the G band of PE-HRG is slightly narrower and shifted to 1582  $\text{cm}^{-1}$ , while the D band at 1343  $\text{cm}^{-1}$  (Fig. 5 black line). A

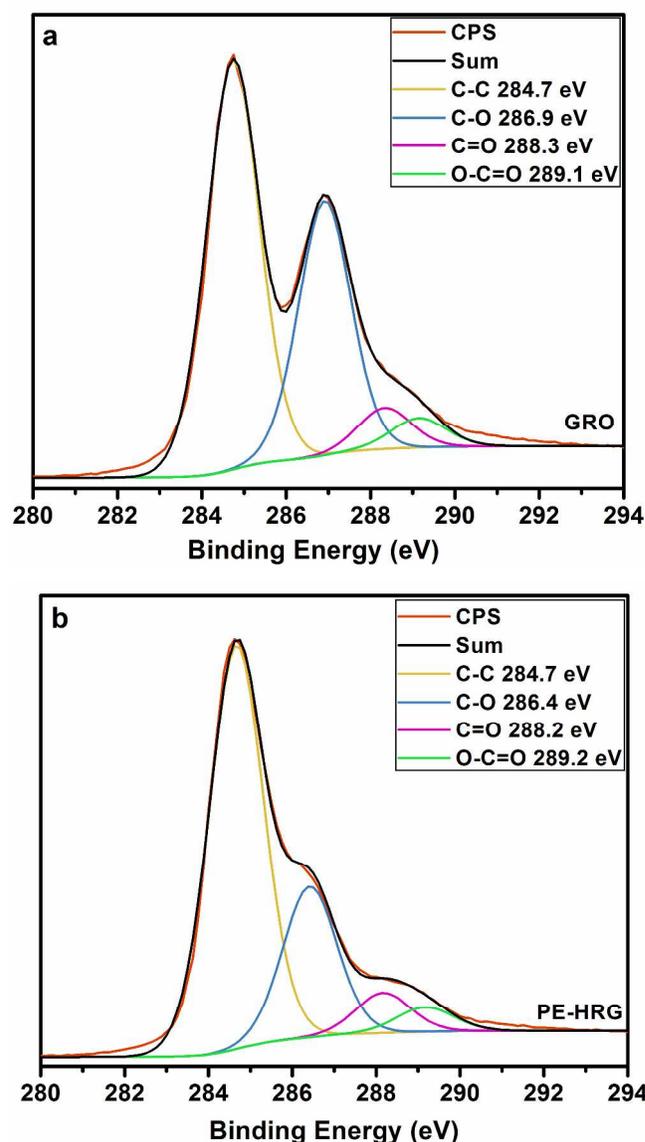

comparison of the Raman spectra of both GO and PE-HRG showed that the G band of PE-HRG had shifted by  $10\text{ cm}^{-1}$  from  $1592$  to  $1582\text{ cm}^{-1}$ , whereas only a slight shift of the D band from  $1346$  to  $1343\text{ cm}^{-1}$  was observed. The shift of the bands of PE-HRG after reduction towards the ideal positions of the G band ( $1575\text{ cm}^{-1}$ ) and D band ( $1350\text{ cm}^{-1}$ ) of graphene is a clear indication of the restoration of the  $\text{sp}^2$  character of PE-HRG, and it is compatible with a high degree of reduction.

**Fig. 5:** Raman spectra of graphene oxide (GRO, red line) and highly reduced graphene oxide (PE-HRG, black line) using plant extract.

XPS can provide valuable information regarding the behavior of oxygen-containing functional groups on the carbon skeleton. In order to demonstrate the reduction of GRO by PE, high resolution C1s spectra of GRO and PE-HRG were measured (Fig 6). The C1s spectrum of GRO displayed four different kinds of signals, which were assigned to  $\text{sp}^2$  carbon C-C bonding of the graphitic structure and oxygen containing functional groups attached to the surface of the GRO due to the oxidation of graphite (e.g. hydroxyl, epoxy, alkoxy and carbonyl (C-O, C=O, O-C=O etc.)). The C1s signals observed at 284.7, 286.9, 288.3 and 289.1 eV are attributed to the  $\text{sp}^2$  carbon C-C, C-O, C=O, and O-C=O groups of GRO, respectively. Peak fitting resulted in atomic concentrations of 55.58, 34.57, 5.62 and 4.23 % for the different groups. Although similar signals also appeared almost at the same positions for PE-HRG-1 after reduction, the intensities of the signals belonging to the oxygen containing functional groups (286.4, 288.2 and 289.2 eV) had a much smaller intensity (Fig 6b bottom), which suggests that the number of oxidized groups on the surface of the GRO sheets decreased significantly after reduction. Peak fitting resulted in atomic concentrations of 65.04, 24.24, 6.54 and 4.17 % for the different groups. It is worth to mention that in spite of decrease in the intensity of the peaks corresponding to oxygen functional groups, the elemental (C/O) ratio in PE-HRG is not as high as reported for the chemically reduced graphene or bio-reduced without stabilizer.<sup>50</sup> This could be due to the fact that PE molecules are also bound to the PE-HRG surfaces (as indicated by UV-Vis and FT-IR data) and contributes to the presence of extra amount of oxygen. Similar results were also obtained by Yan et al. using Gallic acid as reducing and stabilizing agent.<sup>48</sup>

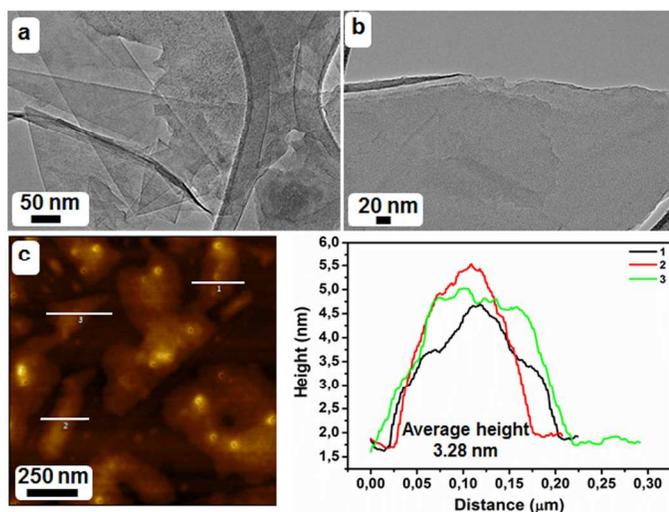

The morphology and layer thickness of the PE-HRG were determined by TEM and AFM (Fig. 7). The TEM images (Fig. 7 a and b) revealed a transparent and sheet-like structure for PE-HRG. A large number of wrinkles and scrolls were observed on the surface of the PE-HRG sheet, which remained stable under the high energy electron beam. We observed that the edges of the suspended graphene layers were folded back, and there was also an indication for the formation of a few graphene layers in high resolution TEM. The AFM height profile taken at 3 different points (Fig. 7c) showed a maximum thickness  $\sim 3.3\text{ nm}$  indicating the presence of 3-4 layers thick sheets and the smallest step height we measured was  $0.9\text{ nm}$  (Fig. S1) which we associate to a single graphene layer situated directly on the mica substrate.<sup>64</sup>

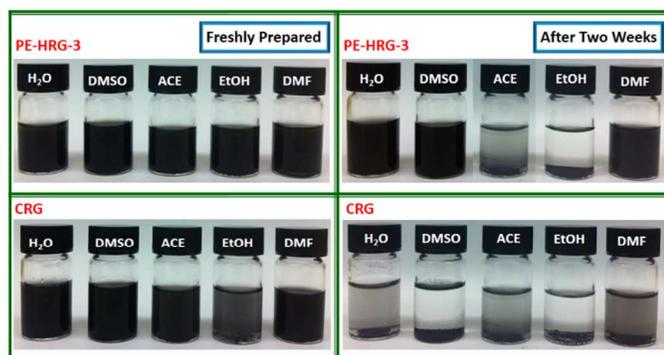

**Fig. 6:** XPS spectra of (top) GRO and (bottom) PE-HRG showing the partial removal of oxygen-containing functional groups from the surface of the GRO.

The formation of stable and homogeneous graphene suspensions in different solvents is a formidable challenge, which is

met with external surfactants or stabilizers including polymers or nanoparticles.<sup>45,48</sup> The bio-reduction of GRO generally avoids the addition of any other surfactant to obtain stable solutions of graphene-type materials. As the role of the *P. glutinosa* PE as bioreductant and stabilizer confirmed our previous results<sup>60,65</sup> we investigated the dispersibilities of the bio-reduced PE-HRG and compared it with that of CRG. For this purpose, freshly produced PE-HRG-1, 2 (Fig. S2), PE-HRG-3 prepared with different amounts (10, 20 and 50 mL) of PE respectively and CRG were dispersed in DI water and other organic solvents (acetone, ethanol, DMSO and DMF, see Fig. 8). The dispersions were prepared by sonicating 5 mg of CRG or PE-HRG in 10 mL of solvent. Superior dispersions were obtained for bio-reduced PE-HRG (compared to CRG). The dispersion quality of PE-HRG was enhanced by increasing the amount of PE. Figure 8 compares the dispersibility of PE-HRG-3 and CRG in five different solvents. After two weeks, the CRG suspensions had become instable, whereas PE-HRG-3 still exhibited excellent dispersibility in most solvents.

**Fig. 7:** TEM images (a,b) of as-prepared PE-HRG at different resolutions, (c) AFM height image of PE-HRG with the corresponding line profiles.

**Fig. 8:** Digital images of the dispersions of PE-HRG-3 (prepared with 50 ml of plant extract), and CRG (prepared with hydrazine hydrate).

## Conclusions

In summary, we described a green and eco-friendly method for the reduction of GRO with *P. glutinosa* PE, which not only acts as bioreductant but also as a stabilizer. Spectroscopic, diffraction and imaging techniques confirmed the partial reduction of GRO to PE-HRG, whereas TEM and AFM indicated the presence of multiple layers of graphene (PE-HRG) in the product. The bio-reduced PE-HRGs exhibited an enhanced dispersibility in various solvents compared to chemically reduced graphene (CRG). The quality and dispersion stability of PE-HRG was improved significantly with higher amounts of PE. The bio-reduction with *P. glutinosa* extract appears to be a useful substitute for conventional reduction methods for the synthesis of highly reduced graphene oxide (HRG). The abundance, easy collection and low cost of *P. glutinosa* plant extract makes it potentially attractive for a large-scale synthesis of graphene and other graphene based materials.
