A novel multifunctional graphene/Fe$_3$O$_4$/TiO$_2$ composite with excellent hydrophilicity and biological compatibility was synthesized and applied to the fast, highly selective and sensitive enrichment of phosphopeptides from the biosamples.

Protein phosphorylation is one of the most significant post-translational modifications (PTMs) in nature, playing a crucial role in eukaryotic cells, involving in many regulatory functions, such as cell growth, differentiation, division, signal transduction and metabolism. Therefore, a comprehensive analysis of protein phosphorylation via the identification of phosphorylation sites is of keen interest in the field of proteomics. In recent years, matrix-assisted laser desorption/ionization mass spectrometry (MALDI-MS) and electrospray-ionization mass spectrometry (ESI-MS), have been widely employed to study PTMs owing to their high sensitivity and high-throughput. However, it is still a great challenge to detect phosphopeptides due to their low abundance and low ionization efficiency. Therefore, the selective enrichment of phosphoproteins or phosphopeptides from complex biosamples is an essential step prior to MS analysis.

To date, immobilized metal ion affinity chromatography (IMAC) has been widely applied to enrich the phosphopeptides. When loaded on IMAC, the chelating metal ions (Fe$^{3+}$, Ga$^{3+}$, Zr$^{4+}$, Ti$^{4+}$) bind specifically to the phosphopeptides from complex mixtures. Nevertheless, the limitation in IMAC-based enrichment is the high level of unspecific binding of acidic peptides. Metal oxide affinity chromatography (MOAC) has emerged to be an attractive alternative to IMAC. Although TiO$_2$-based MOAC materials have been the most commonly used for the enrichment of phosphopeptides, owing to its high chemical stability over a wide pH range, selectivity and recovery, and relatively high salt tolerance, the aggregation of TiO$_2$ particles limits the available surface area of adsorbent for the efficient enrichment.

Graphene, an sp$^2$-bonded carbon sheet with the thickness of a single atom, has attracted a great deal of attention in recent years due to its unique mechanical, thermal, optical and electrical properties. With the inherent superiorities, graphene has been successfully utilized as a good adsorbent in sample pretreatment based on its ultrahigh specific surface area, high loading capacity, large delocalized π-electron system and hydrophobic interaction. However, its poor hydrophilicity and difficulty in the surface functionalization often limit its more extensive bioapplication. Recently, Ti$^{4+}$ or TiO$_2$ immobilized graphene can be used as the adsorbent for the selective extraction of phosphopeptides from complex peptides mixtures. The direct use of graphene as an adsorbent needs a complicated process to isolate the graphene and targets from the samples. Decorating magnetic iron oxide nanoparticles onto graphene in a composite will facilitate to impart the desirable magnetic property into graphene in a variety of application fields, such as bioseparation, medical diagnosis, magnetically targeted drug delivery, magnetic energy storage and catalysis.

Herein, we designed a facile synthetic strategy of graphene/Fe$_3$O$_4$/TiO$_2$ multifunctional composite material for the enrichment of phosphopeptides (Scheme 1). The graphene/Fe$_3$O$_4$/TiO$_2$ multifunctional composite exhibited several attractive advantages. Firstly, the large specific surface area of graphene offers higher capacity for loading the TiO$_2$ nanoparticles and thus possesses the high available surface area for the efficient enrichment of phosphopeptides. Second, the hydrophilic polydopamine layer on the magnetic graphene exhibits excellent environmental stability, good biocompatibility and good water dispersibility, and also decreases the non-specific adsorption of non-phosphopeptides. Finally, the highly loaded Fe$_3$O$_4$ nanoparticles accelerate the isolation. The resulting graphene/Fe$_3$O$_4$/TiO$_2$ composite can selectively capture, fast magnetically isolate and sequentially determine the low-abundance phosphopeptides from the complex biosamples.

The synthetic strategy of graphene/Fe$_3$O$_4$/TiO$_2$ magnetic multifunctional composite and the procedure for the selective enrichment of phosphopeptides are illustrated in Scheme 1. The graphene/Fe$_3$O$_4$ composite was firstly prepared by a modified solvoethermal method. The surface modified graphene oxide (GO) highly loaded with Fe$_3$O$_4$ nanoparticles is hydrothermally produced from the reduction reaction between FeCl$_3$ and ethylene glycol in the presence of GO. Then, the polydopamine (PDA)-capped graphene/Fe$_3$O$_4$ was prepared via the self-polymerization of dopamine hydrochloride. Dopamine, commonly known as a neuroendocrine transmitter and a unique molecule mimicking
the adhesives proteins, exhibits excellent affinity for most organic and inorganic surfaces such as metal, metal oxide, and polymer surfaces and has been found to be able to polymerize into a unique hydrophilic PDA coating on a variety of substrates at a weak alkaline pH.\textsuperscript{14} Moreover, as a good reducing agent, dopamine has recently been used to fabricate nanocomposites \textit{via} directly reacting with HAuCl\textsubscript{4}.\textsuperscript{15} Finally, graphene/Fe\textsubscript{3}O\textsubscript{4}/TiO\textsubscript{2} multifunctional composites were obtained by the hydrolysis of Ti\textsuperscript{4+} immobilized on the PDA (see experimental details in ESI).

![TEM images](image)

**Fig.1** TEM images of graphene/Fe\textsubscript{3}O\textsubscript{4} (a) and graphene/Fe\textsubscript{3}O\textsubscript{4}/TiO\textsubscript{2} (b) magnetic composite.

The TEM images of graphene/Fe\textsubscript{3}O\textsubscript{4} and graphene/Fe\textsubscript{3}O\textsubscript{4}/TiO\textsubscript{2} composites are shown in Fig.1. Obviously, the two-dimensional graphene sheets are well decorated by a large quantity of uniform spherical and evenly distributed Fe\textsubscript{3}O\textsubscript{4} particles (with average size of about 150 nm). The TEM image of graphene/Fe\textsubscript{3}O\textsubscript{4}/TiO\textsubscript{2} (Fig.1b) clearly reveals that the TiO\textsubscript{2} nanoparticles with average diameter of 2 nm highly loaded on the surface of PDA-graphene/Fe\textsubscript{3}O\textsubscript{4}. It is clear that the plane structure of graphene/Fe\textsubscript{3}O\textsubscript{4} was well retained due to the good chemical and physical stability of graphene, and the functional layer of PDA was successfully coated on graphene and Fe\textsubscript{3}O\textsubscript{4}.

The successful synthesis of graphene/Fe\textsubscript{3}O\textsubscript{4}/TiO\textsubscript{2} can be further confirmed by Fourier transform infrared spectroscopy (FT-IR), X-ray photoelectron spectroscopy (XPS), and power X-ray diffraction (XRD) analysis. The band at 1083 cm\textsuperscript{-1} and 877.7 cm\textsuperscript{-1} was attributed to C–O stretching of the epoxy structure in GO, while the bands at 1618.2 cm\textsuperscript{-1} and 1187.5 cm\textsuperscript{-1} can be attributed to the stretching vibrations of C–O in asymmetric and symmetric COO\textsuperscript{-} on the graphene/Fe\textsubscript{3}O\textsubscript{4} (Fig.S1, ESI). After coating with polydopamine, the bands at 1083 and 877.7 cm\textsuperscript{-1} disappear, and many new peaks can be seen in PDA-graphene/Fe\textsubscript{3}O\textsubscript{4} (Fig. S1b, ESI). The peak at 1203 cm\textsuperscript{-1} was assigned to the C–O stretching of phenolic groups in polydopamine, which indicated that graphene/Fe\textsubscript{3}O\textsubscript{4} had been successfully modified by PDA coating. It was obvious that C, O, Fe, Si, N and Ti all appeared on the surface of graphene/Fe\textsubscript{3}O\textsubscript{4}/TiO\textsubscript{2} composite from XPS patterns (Fig.S2a, ESI). A Cls peak around 291.7 eV, O1s peak at 530.6 eV, N1s peak at 398.5 eV, Fe2p peak at 710.2 eV and Ti2p peaks at 459.6 and 453.9 eV can be observed. By the deconvolution of C\textsubscript{1s} spectrum, three peaks at 284.59, 286.39 and 288.59 eV were identified, which are assigned to the C–C or C–H, C–N or O–C, C–C, and benzene rings respectively (Fig.S2b, ESI). The XRD results show that the diffraction peaks of graphene/Fe\textsubscript{3}O\textsubscript{4}/TiO\textsubscript{2} matched well with those of magnetite (ICPDS No. 75-1610) (Fig.S3, ESI). This suggests the synthetic process did not change the crystalline phase of magnetite. The magnetic properties of graphene/Fe\textsubscript{3}O\textsubscript{4}/TiO\textsubscript{2} composite were studied using a vibrating sample magnetometer (VSM). The magnetic hysteresis loops show that graphene/Fe\textsubscript{3}O\textsubscript{4}/TiO\textsubscript{2} composite has a fairly strong magnetization (Fig.S4, ESI) and can be rapidly separated from the mixture within 1 min in the presence of an external magnet (Fig.S4 inset, ESI).

The enrichment performance of graphene/Fe\textsubscript{3}O\textsubscript{4}/TiO\textsubscript{2} composite for phosphopeptides was first examined by the tryptic digest product of β-casein. From the direct analysis of the digest product (20 fmol), it can be seen that only three weak signals of them originating from phosphopeptides could be detected, while the peaks corresponding to nonphosphorylated peptides dominate (Fig.2a). After the enrichment using graphene/Fe\textsubscript{3}O\textsubscript{4}/TiO\textsubscript{2} composite, the signals of those at m/z 1981.8, 2061.8, 2432.0, 2556.8 and 3042.2 which represent phosphopeptide residues derived from β-casein\textsuperscript{16} can be found (Fig.2b). Table S1 (ESI) lists the detailed amino acid sequences of these identified phosphopeptides. When the amount of the digest product decreases to 20 amol and 2 amol, the phosphopeptide peaks at m/z 1981.8, 2061.8, 2556.8 and 3122.1 which represent phosphopeptide residues derived from β-casein\textsuperscript{16} can be found (Fig.2b). Table S1 (ESI) lists the detailed amino acid sequences of these identified phosphopeptides. When the amount of the digest product decreases to 0.2 amol, it is difficult to distinguish the peaks because of the background (Fig.S5, ESI). The results indicate that graphene/Fe\textsubscript{3}O\textsubscript{4}/TiO\textsubscript{2}
multifunctional composite can specifically extract and completely elute phosphopeptides from the digest solution with high sensitivity.

The capacity of graphene/Fe$_3$O$_4$/TiO$_2$ composite to selectively trap phosphopeptides was further investigated by analyzing the mixture of tryptic digests of β-casein (20 fmol) and BSA at molar ratio of 1:100, 1:500. As shown in Fig.S6a (ESI), nearly no phosphopeptide signal can be observed in the β-casein/BSA tryptic digest mixture at molar ratio of 1:100. Because the introduction of BSA dramatically increases the complexity of the sample, the signals of phosphopeptides are severely suppressed by the greater amount of nonphosphopeptides largely originating from BSA. However after the enrichment with graphene/Fe$_3$O$_4$/TiO$_2$ composite, five intensive peaks corresponding to specific phosphopeptides of β-casein are observed. When adjusting β-casein/BSA to 1:500 with the concentration of β-casein kept at 20 fmol, after the enrichment, the mass spectra revealed that three signals of phosphopeptides of m/z at 2061.8, 2556.1 and 3122.3 (Fig.S6c, ESI) can be still observed under the clear background. This proves that graphene/Fe$_3$O$_4$/TiO$_2$ composite possesses the excellent capability for the selective enrichment of phosphopeptides from a complex in the presence of large excess of nonphosphopeptide.

![Fig.3 MALDI-MS spectra of the tryptic digest of nonfat milk obtained by direct analysis (a), and after enrichment by graphene/Fe$_3$O$_4$/TiO$_2$ composite (b). Peaks of α-casein phosphopeptides are marked with *, and those of β-casein are marked with #.](image)

It is demonstrated that the graphene/Fe$_3$O$_4$/TiO$_2$ composite can be applied in the enrichment of phosphopeptides from the tryptic digest of nonfat milk commonly containing α-casein and β-casein. As shown in Fig. 3a, before the enrichment, only a few signals with low intensity were identified, which are almost submerged by those of nonphosphopeptides. However, after the enrichment using graphene/Fe$_3$O$_4$/TiO$_2$ composite, eleven phosphopeptide peaks were identified (seven from α-casein and four from β-casein) with good resolution (Fig. 3b) and the corresponding sequences were listed in Table S2 (ESI). This result demonstrated that graphene/Fe$_3$O$_4$/TiO$_2$ composite can be successfully used for the selective enrichment of phosphopeptides from a very complex real sample.

In summary, a new type of graphene/Fe$_3$O$_4$/TiO$_2$ composite with excellent hydrophilicity and biological compatibility has been synthesized. The multifunctional material was successfully used to highly selectively and sensitively enrich phosphopeptides. Thus, there is promise that the newly synthesized graphene/Fe$_3$O$_4$/TiO$_2$ composite enables a more efficient enrichment of phosphopeptides from a complex peptide mixture in phosphoproteome research.
