This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

*Accepted Manuscripts* are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. This *Accepted Manuscript* will be replaced by the edited, formatted and paginated article as soon as this is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

**Abstract:** Polyurethane- $\text{Al}_2\text{O}_3$  organic-inorganic anion-exchange fibrous composites were prepared by simple stirring with magnetic bar in different stoichiometric ratios of polyurethane and  $\text{Al}_2\text{O}_3$ . The structure and morphology of the prepared fibrous composite were ascertained by fourier transform spectroscopy (FTIR), field emission scanning electron microscopy (FE-SEM), thermal analysis (TGA and DTG) and X-ray diffraction analysis (XRD). The material was found to be highly desirable for electroanalytical application as ionic sensor, its membrane electrode have been developed for the detection of Cr(VI) in aqueous solutions. The membrane electrode shows the best result with linear potential response in the concentration range of  $1 \times 10^{-1}$  mol L<sup>-1</sup> to  $1 \times 10^{-8}$  mol L<sup>-1</sup> of Cr(VI) ion with a slope of 30.36 mV/decade. The selectivity coefficients values for interfering ions indicate good selectivity for Cr(VI) over interfering anions. The accuracy of the procedure has been tested on chromium-free drinking water samples spiked with known amount of Cr(VI) and results were comparable to these generated by AAS (Atomic absorption spectroscopy).

**Keywords:** polymer, fibrous composite, anion exchanger, Cr(VI) selective electrode.

## 1 **1. Introduction**

2 Chromium and its compounds have been widely used in different commercial ventures, such as  
3 mining, tanning, concrete, generation of steel or other metal compounds, electroplating  
4 operations, photographic materials, destructive painting, metal businesses etc. [1-2].  
5 Epidemiological studies conveyed in the UK, Europe, Japan and the US have reliably  
6 indicated that specialists in the chromate generation industry have high risk of respiratory  
7 illness, fibrosis, puncturing of the nasal septum, advancement of nasal polyps and lung disease  
8 [3]. In the watery environment chromium can exist in either as Cr(VI) or Cr(III) of which, the  
9 Cr(VI) is known to be profoundly lethal, mutagenic and cancer-causing [4-6]. Its vicinity in  
10 nature also poses huge risk to oceanic life and also to open wellbeing [5, 7]. As per the standards,  
11 the maximum permissible limit of Cr(VI) for discharge to inland surface water and portable  
12 water is  $0.1 \text{ mg L}^{-1}$  and  $0.05 \text{ mg L}^{-1}$  respectively [7-8]. In perspective of such poisonous impacts  
13 of Cr(VI), its checking and regulation in ecological specimens is of utmost importance.

14 A lot many sophisticated techniques such as spectrophotometry [9], spectrofluorimetry [10], ion  
15 chromatography coupled with atomic absorption spectroscopy [11], differential pulse  
16 polarography [12] and differential pulse voltammetry [13] have generally been utilized for the  
17 determination of trace amount of Cr(VI) in waste water and other water bodies. However, most  
18 of these techniques suffer from many disadvantages such as high cost, unsuitability for routine  
19 analyses of large number of analysis and non-applicability in field work. Recently, ion-selective  
20 electrode have provided a solution to many of these problems due to its portability, high  
21 sensitivity and low cost which gives a convenient, quick and online strategy for the  
22 determination of Cr(VI). A number of works have described the fabrication of ion-selective

1 membrane electrode using organic-inorganic composite ion-exchange materials [14-15]. Among  
2 organic polymers, polyurethane has received significant interest of researchers as it is widely  
3 used in fabricating fibrous precursors and also shows high environmental stability in comparison  
4 to other polymers [16-21]. It finds wide variety of applications such as metal ion adsorption [22],  
5 separation of organic liquids, organic vapors and water [23]. A few reports on polymeric  
6 organic-inorganic cation exchange fibrous composite materials with their electroanalytical  
7 applications have already been published [24-25]. However, organic-inorganic anion exchange  
8 fibrous composite materials have been poorly reported in literatures and thus more research work  
9 needs to be focused in this area. Literature survey reveals that the alumina ( $\text{Al}_2\text{O}_3$ ) is amphoteric  
10 in nature and thus can be used as cation and anion exchanger [26].  $\text{Al}_2\text{O}_3$  modified with  
11 polymers was proposed to be used in chromatographic ion exchange separations and can be  
12 exploited for the preparation of anion exchange materials. Owing to the advantageous properties  
13 of both polyurethane and  $\text{Al}_2\text{O}_3$  it is of much interest to prepare the organic-inorganic anion  
14 exchange fibrous composite based on polyurethane and  $\text{Al}_2\text{O}_3$  by an ecofriendly route for  
15 making ion-selective membrane electrode. However determination of anions above the  
16 permissible limit is also important from ecological point of perspective. Potentiometric  
17 method employing an ion sensor or ion-selective membrane electrode is an alternative, simple  
18 and low cost method for determination of Cr(VI). Thus, in this work, a new Cr(VI) selective  
19 electrode based on polyurethane- $\text{Al}_2\text{O}_3$  anion exchange fibrous composite is prepared and  
20 characterized for the potentiometric determination of Cr(VI).

21

22

## 1 2. Experimental

### 2 2.1 Reagents and chemicals

3 For the preparation of anion exchange fibrous composite the main chemical were used:  $\text{Al}_2\text{O}_3$  (E-  
4 Merck, India), polyurethane from Research, design and standard organization, India,  
5 tetrahydrofuran (Qualigens, India) and potassium dichromate ( $\text{K}_2\text{Cr}_2\text{O}_7$ ) from Qualigens (India  
6 Ltd.). All other reagents and chemicals were of analytical grade (AR).

### 7 2.2 Preparation of polyurethane- $\text{Al}_2\text{O}_3$ anion exchange fibrous composites

8 Fibrous polyurethane- $\text{Al}_2\text{O}_3$  anion exchange composites were synthesized in different weight  
9 ratio of  $\text{Al}_2\text{O}_3$  with polyurethane by putting in on vigorous stirring conditions [27-28]. In a  
10 typical process, 500 mg polyurethane was dissolved in tetrahydrofuran (THF) at room  
11 temperature to which different amounts of  $\text{Al}_2\text{O}_3$  (100, 200, 300, 400 and 500 mg) were  
12 dispersed. The dispersion was put under mechanical stirring for 24h at room temperature which  
13 gave homogeneous  $\text{Al}_2\text{O}_3$  dispersed in polyurethane solution. The above  $\text{Al}_2\text{O}_3$  dispersed  
14 polyurethane solution was dropped in water (DMW) with the help of needle syringe under  
15 vigorously stirring resulting in fibrous composite which accumulated on the surface of the water.  
16 Thus prepared fibrous polyurethane- $\text{Al}_2\text{O}_3$  composite were filtered, washed with doubly distilled  
17 water and later dried at room temperature. The dried fibrous composite was converted into  $\text{Cl}^-$   
18 form by treating with  $1 \text{ mol L}^{-1}$   $\text{NaCl}$  for two days with occasional shaking and intermittently  
19 replacing the supernatant liquid with fresh  $1 \text{ mol L}^{-1}$   $\text{NaCl}$  two to three times. The excess was  
20 removed after several washings with DMW (demineralized water) and finally dried at room  
21 temperature. The condition of preparation and the ion-exchange capacity (IEC), of the anion

1 exchange fibrous composite are given in Table 1. A schematic representation of the formation of  
2 polyurethane- $\text{Al}_2\text{O}_3$  fibrous composite is shown in Scheme 1.

### 3 **2.3 Ion-exchange capacity (IEC) measurements**

4 IEC of the anion exchange fibrous composite samples in the  $\text{Cl}^-$  form were determined using the  
5 Mohr method [29]. Accurately weighed dry exchanger was converted in to  $\text{Cl}^-$  ionic form  
6 through immersion in  $1 \text{ mol L}^{-1}$  NaCl for two days. Excess NaCl was washed off and then the  
7 AEFC were immersed in  $200 \text{ mL } 0.5 \text{ mol L}^{-1}$   $\text{Na}_2\text{SO}_4$ . The amount of  $\text{Cl}^-$  was determined using  
8 titration with  $\text{AgNO}_3$ ; anion exchange values were obtained and expressed as  $\text{meq g}^{-1}$  of dry  
9 exchanger (In  $\text{Cl}^-$  form).

## 10 **2.4. Characterizations**

### 11 **2.4.1. Fourier transform infra red (FTIR) studies**

12 The FTIR spectrum of polyurethane,  $\text{Al}_2\text{O}_3$  and polyurethane- $\text{Al}_2\text{O}_3$  fibrous composite were  
13 obtained by FTIR spectrophotometer (Perkin-Elmer, USA, model Spectrum-BX) by KBr disc  
14 method at room temperature.

### 15 **2.4.2. X-Ray diffraction analysis**

16 X-Ray diffraction patterns (XRD) of polyurethane,  $\text{Al}_2\text{O}_3$  and polyurethane- $\text{Al}_2\text{O}_3$  fibrous  
17 composite were obtained by PHILIPS PW1710 instrument equipped with a Cu anode, automatic  
18 divergence slit and a graphite monochromator, under the following experimental conditions:  
19  $\text{CuK}\alpha$  radiation,  $1.54 \text{ \AA}$ ; generator tension, 45 kV; generator current, 40 mA; intensity ratio  
20  $(\alpha_2/\alpha_1)$ , 0.500.

### 1 **2.4.3. Field emission Scanning electron microscopy (SEM) studies**

2 The surface morphology of polyurethane, Al<sub>2</sub>O<sub>3</sub> and polyurethane-Al<sub>2</sub>O<sub>3</sub> fibrous composite were  
3 studied by field emission scanning electron microscopy (FE-SEM) using a LEO microscope  
4 (435–VF) at various magnifications.

### 5 **2.4.4. Thermal studies**

6 The thermal stability of polyurethane, Al<sub>2</sub>O<sub>3</sub> and polyurethane-Al<sub>2</sub>O<sub>3</sub> fibrous composite were  
7 studied by TGA and DTG techniques using thermal analyzer-EXSTAR TG/DTA 6300. The  
8 samples (10.00 mg of each) were heated in alumina crucible from 30 to 1000 °C at the rate of 10  
9 °C min<sup>-1</sup> in the nitrogen atmosphere at the flow rate of 200 mL min<sup>-1</sup>.

## 10 **2.5 Preparation of polyurethane-Al<sub>2</sub>O<sub>3</sub> fibrous composite membranes**

11 Polyurethane-Al<sub>2</sub>O<sub>3</sub> anion exchange fibrous composite membranes were prepared in various  
12 weight ratios of constituting components by simple solution casting method. Different weight  
13 ratios of polyurethane-Al<sub>2</sub>O<sub>3</sub> (100, 150 and 200 mg) were dispersed in THF at room temperature.  
14 Mechanical stirring was applied for 6h at room temperature in order to obtain well dispersed  
15 composite solution. Thus obtained polyurethane-Al<sub>2</sub>O<sub>3</sub> dispersed solution was casted onto clean  
16 glass plates and kept for 48 h at room temperature for complete evaporation of THF. The  
17 resultant composite membranes were cautiously peeled out of the glass plate, rinsed with doubly  
18 distilled water on both sides, dried at room temperature and later stored in desiccator to further  
19 experiments.

20

## 1 **2.6 Physicochemical characterization of polyurethane-Al<sub>2</sub>O<sub>3</sub> fibrous composite membranes**

2 The Water content (% total wet weight), porosity, thickness and swelling etc. were determined  
3 by the same method as discussed in our previous studies [14]. Those membrane which exhibited  
4 good surface qualities like porosity, thickness and swelling etc. were selected for further  
5 investigation.

## 6 **3. Fabrication and conditioning of ion-selective membrane electrode**

7 The ion-selective membrane electrode was fabricated by the same method as we have described  
8 previously [14]. The membrane sheet of 0.145 mm thickness as obtained by the above procedure  
9 was cut in the shape of disc and mounted at the lower end of a Pyrex glass tube (outer diameter  
10 0.8 cm, internal diameter 0.6 cm) with araldite. Finally, the assembly was allowed to dry in air  
11 for 24 h. The glass tube was filled with 0.1 mol L<sup>-1</sup> potassium dichromate solution. Electrode  
12 was then equilibrated with Cr(VI) solution (0.1 mol L<sup>-1</sup>) for 5-7 days. The tube was filled 3/4th  
13 with potassium dichromate solution (0.1 mol L<sup>-1</sup>) and then immersed in a beaker containing the  
14 test solution of varying concentration of Cr(VI) ion, keeping the level of inner filling solution  
15 higher than the level of the test solution to avoid any reverse diffusion of the electrolyte.

### 16 **3.1. Potential measurements**

17 All the potential measurements were carried out using the following cell assembly:

19 A saturated calomel electrode (SCE) was inserted in the tube for electrical contact and other  
20 saturated calomel electrode (SCE) was employed as an external reference electrode.  
21 Potentiometric measurements were observed for a series of standard solutions of potassium  
22 dichromate (10<sup>-12</sup>–10<sup>-1</sup> mol L<sup>-1</sup>), set up by gradual dilution of the stock solution, as defined by

1 IUPAC Commission for Analytical Nomenclature [30]. The calibration graphs of potential  
2 versus logarithm of dichromate ion concentration were plotted.

### 3 **3.2. Characteristics of the electrode**

4 The characteristics of the fabricated membrane electrode such as the effect of pH, response time,  
5 potentiometric selectivity coefficient and storage of electrodes were measured by the methods as  
6 described earlier [14].

#### 7 *3.2.1. Effect of pH*

8 Solutions with pH ranging from 1-6 were prepared at  $1 \times 10^{-5}$  mol L<sup>-1</sup> constant ion concentration.  
9 The value of electrode potential at each pH was recorded and plot of electrode potential versus  
10 pH was plotted.

#### 11 *3.2.2. The response time*

12 The method of determining response time in the present work is being outlined as follows. The  
13 electrode is first dipped in a  $1 \times 10^{-5}$  mol L<sup>-1</sup> solution of potassium dichromate and then 10 fold  
14 higher concentrations. The potential of the solution was read at zero second; just after dipping of  
15 the electrode in the second solution and subsequently recorded at the intervals of 10 s. The  
16 potentials were then plotted vs. the time.

#### 17 *3.2.3. Potentiometric selectivity coefficient*

18 In the present work the potentiometric selectivity coefficient ( $K_{AB}^{\text{pot}}$ ) of interfering anions was  
19 determined by using the mixed solution method [31]. The selectivity coefficient was calculated  
20 using the equation given below:

$$21 \quad K_{AB}^{\text{pot}} = a_A / (a_B)^{z_A/z_B} \quad \dots\dots\dots(2)$$

1 where  $a_A$  and  $a_B$  activities of primary and interfering ion and  $z_A$  and  $z_B$  are charges on the ions.

### 2 3.2.4. Storage of electrodes

3 The membrane electrode was stored in distilled water when not in use for more than one day. It  
4 was activated with (0.1 mol L<sup>-1</sup>) Cr(VI) solution by keeping immersed in it for 2 h, before use,  
5 to compensate for any loss of metal ions in the membrane phase that might have taken place due  
6 to a long storage in distilled water. Electrode was then washed thoroughly with DMW before  
7 use.

## 8 4. Results and discussion

9 Various samples of organic-inorganic polyurethane-Al<sub>2</sub>O<sub>3</sub> anion exchange fibrous composites  
10 were prepared by stirring with magnetic bar [27-28] under different stoichiometric ratios.  
11 Although we have prepared a variety of anion exchange fibrous composites by varying the  
12 stoichiometry between polyurethane and Al<sub>2</sub>O<sub>3</sub> but highest anion exchange capacity was  
13 observed in 1:1 stoichiometry (Table 1). Due to higher ion-exchange capacity and thermal  
14 stabilities, sample AEFC-5 (Table 1) was selected for further studies. All polyurethane-Al<sub>2</sub>O<sub>3</sub>  
15 anion exchange fibrous composites samples were in white color, light weight and suitable for use  
16 in the ion-exchange process. The proposed mechanistic representation of formation of  
17 polyurethane-Al<sub>2</sub>O<sub>3</sub> fibrous composite showing interaction of Al<sub>2</sub>O<sub>3</sub> with polyurethane is shown  
18 in Scheme 2.

### 19 4.1. FT-IR spectroscopic analysis

20 The FTIR spectra of polyurethane, Al<sub>2</sub>O<sub>3</sub>, and polyurethane-Al<sub>2</sub>O<sub>3</sub> anion exchange fibrous  
21 composite are shown in Fig. 1. In the polyurethane spectrum, the absorption band at 3333

1  $\text{cm}^{-1}$  corresponds to NH stretching. The sharp peaks at  $2874 \text{ cm}^{-1}$  and  $2959 \text{ cm}^{-1}$  are associated  
2 with  $-\text{CH}_2$  stretching, while other modes of  $-\text{CH}_2$  vibrations are identified by the bands at 1457,  
3 1415, 1311, and  $1228 \text{ cm}^{-1}$ . In addition, the absorption band at  $1735 \text{ cm}^{-1}$  is associated with a  
4 C=O group in polyurethane. The group of NH vibrations is identified by the bands at  $1532 \text{ cm}^{-1}$ .  
5 The band at  $1703 \text{ cm}^{-1}$  is assigned to hydrogen bonding between N-H and C=O groups in the  
6 hard segment and the ester or ester-oxygen groups of the soft segments of urethane linkage. The  
7 presence of  $\text{Al}_2\text{O}_3$  in the polyurethane- $\text{Al}_2\text{O}_3$  fibrous composite is further strengthening from the  
8 presence of broad band at  $3400 \text{ cm}^{-1}$  which may be due to the vibration of hydroxyl groups. The  
9 bands at 757 and  $588 \text{ cm}^{-1}$  due to the stretching vibration of Al-O bond in polyurethane-  $\text{Al}_2\text{O}_3$   
10 fibrous composite. Compared with Fig. 2(a), some peaks are shifted in the polyurethane- $\text{Al}_2\text{O}_3$   
11 fibrous composite from 1248, 1595, 2010,  $2250 \text{ cm}^{-1}$ , to 1100, 1250, 1600,  $1785 \text{ cm}^{-1}$   
12 respectively, indicating the formation of polyurethane- $\text{Al}_2\text{O}_3$  fibrous composite.

#### 13 **4.2. Field emission scanning electron microscopy (FE-SEM) studies**

14 Fig. 2 shows the FE-SEM image of polyurethane and polyurethane- $\text{Al}_2\text{O}_3$  anion exchange  
15 fibrous composite at different magnifications, indicating the binding of inorganic material i.e.  
16  $\text{Al}_2\text{O}_3$  with organic polymer i.e. polyurethane. The images showed the difference in surface  
17 morphology of organic polymer, inorganic material and composite fibers. It has been revealed  
18 that after binding of polyurethane with  $\text{Al}_2\text{O}_3$ , the morphology has been changed. Fig. 2(b-d)  
19 shows the fibrous composite were randomly distributed to form the fibrous web. The  
20 polyurethane- $\text{Al}_2\text{O}_3$  anion exchange fibrous composites were observed soft and flexible.

21

### 1 **4.3. X-ray diffraction (XRD) analysis**

2 Fig. 3 illustrates the XRD pattern of pure polyurethane and polyurethane- $\text{Al}_2\text{O}_3$  anion exchange  
3 fibrous composite in the  $2\theta$  range between 5 and 70 degree. In the XRD pattern of pure  
4 polyurethane there is no sharp diffraction peaks, confirming their non-crystalline nature. The  
5 polyurethane is known to be an amorphous polymer and shows a broad peak at  $2\theta$  value  $17^\circ$ .  
6 However, in the case  $\text{Al}_2\text{O}_3$  of some peaks can be observed at  $15^\circ$ ,  $35.5^\circ$ ,  $45.1^\circ$ ,  $60^\circ$  and  $68^\circ$ . On  
7 the addition of  $\text{Al}_2\text{O}_3$  in the polyurethane matrix, the XRD spectra of polyurethane- $\text{Al}_2\text{O}_3$  anion  
8 exchange fibrous composite clearly exhibit the major peaks of polyurethane and  $\text{Al}_2\text{O}_3$  indicating  
9 the successful incorporation of  $\text{Al}_2\text{O}_3$  in polyurethane- $\text{Al}_2\text{O}_3$  anion exchange fibrous composite.

### 10 **4.4. TGA and DTG analysis**

11 Fig. 4a shows a comparison of mass losses of pure polyurethane,  $\text{Al}_2\text{O}_3$  and polyurethane- $\text{Al}_2\text{O}_3$   
12 fibrous composite upon heating in nitrogen atmosphere. Pure polyurethane was initially stable up  
13 to  $150^\circ\text{C}$  (0.91% mass loss, probably due to physisorbed water evaporated at this temperature);  
14 thereafter gradual weight loss with the same rate up to about  $500^\circ\text{C}$  (88.11% mass loss), takes  
15 place by heat adsorption, is ascribed to the degradation of the polymers unsaturated groups. In  
16 the case of  $\text{Al}_2\text{O}_3$ , the first weight loss was observed at  $100^\circ\text{C}$  (2.41%) due to removal of  
17 external water molecules and next on  $300^\circ\text{C}$  (2.98%) and after  $400^\circ\text{C}$  the  $\text{Al}_2\text{O}_3$  was found  
18 stable up to  $1000^\circ\text{C}$  with 2.84% further mass loss. However in case of polyurethane- $\text{Al}_2\text{O}_3$   
19 fibrous composite the first weight loss at  $200^\circ\text{C}$  (1.22% weight loss) due to removal of external  
20 water molecules and second weight loss up to  $500^\circ\text{C}$  (54.09 % weight loss) because of

1 degradation of polyurethane and after 500 °C the polyurethane- $\text{Al}_2\text{O}_3$  fibrous composite remain  
2 stable up to 1000 °C with 3.88% further mass loss. It can be concluded from Fig. 4a that the  
3 thermal stability of the polyurethane- $\text{Al}_2\text{O}_3$  fibrous composite is better than that of pure  
4 polyurethane. The total mass loss up to 1000 °C has been estimated to be about 92.87%, 8.23%  
5 and 59.19% for polyurethane,  $\text{Al}_2\text{O}_3$  and polyurethane- $\text{Al}_2\text{O}_3$  fibrous composite respectively.  
6 These results confirm that the presence of  $\text{Al}_2\text{O}_3$  in polyurethane- $\text{Al}_2\text{O}_3$  fibrous composite is  
7 responsible for the higher thermal stability of the composite material in comparison to pristine  
8 polyurethane.

9 DTG analysis of pure polyurethane,  $\text{Al}_2\text{O}_3$  and polyurethane- $\text{Al}_2\text{O}_3$  fibrous composite was  
10 studied as a function of rate of weight loss ( $\mu\text{g min}^{-1}$ ) versus temperature (Fig. 4b). In case of  
11 pure polyurethane decomposition at 287 °C and 356 °C was found with 260  $\mu\text{g min}^{-1}$  and 910  $\mu\text{g}$   
12  $\text{min}^{-1}$  weight loss, respectively and in case of  $\text{Al}_2\text{O}_3$  decomposition at 53 °C and 258 °C was  
13 found with 35  $\mu\text{g min}^{-1}$  and 34  $\mu\text{g min}^{-1}$  weight loss, respectively. However, in the case of  
14 polyurethane- $\text{Al}_2\text{O}_3$  fibrous composite, the decomposition was observed at 306 °C and 368 °C  
15 with 360 and 540  $\mu\text{g min}^{-1}$  weight loss, respectively. Thus, it could be concluded from the DTG  
16 studies that the rate of thermal decomposition was higher in the case of pristine polyurethane,  
17 where as in the case of polyurethane- $\text{Al}_2\text{O}_3$  composite, the rate of thermal decomposition is  
18 lower. The better thermal resistance of polyurethane- $\text{Al}_2\text{O}_3$  fibrous composite was due to  
19 incorporation of  $\text{Al}_2\text{O}_3$  composite in the polyurethane matrix.

20

21 ***4.5. Physicochemical properties of polyurethane- $\text{Al}_2\text{O}_3$  fibrous composite membrane***

1 The thickness, swelling, porosity, water content capacity etc. of the polyurethane- $\text{Al}_2\text{O}_3$  anion  
2 exchange fibrous composite membrane was investigated and the results are summarized in Table  
3 2. It was noted that as the amount of illustrative components of the membrane, i.e. polyurethane-  
4  $\text{Al}_2\text{O}_3$  increased, the thickness, swelling, water content, porosity increased. Therefore, the lower  
5 orders of water content, swelling and porosity with less thickness of this membrane suggest that  
6 the interstices are negligible and diffusion across the membrane would occur primarily through  
7 the exchange sites. Hence, membrane sample AEFCM-1 (thickness 0.145 mm) was selected for  
8 the preparation of an ion-selective electrode for further studies. Nevertheless, further various  
9 characteristics are necessary for a membrane ion-selective electrode to be regarded as a suitable  
10 sensor for the quantitative measurement of ions. The most important features are the slope,  
11 working concentration range, response time, pH, selectivity and life span of the membrane  
12 electrode.

13 Membrane of polyurethane- $\text{Al}_2\text{O}_3$  anion exchange fibrous composite carry positive charges due  
14 to the interaction between the nitrogen on the polymer backbone and Al of  $\text{Al}_2\text{O}_3$  as given in  
15 Scheme 2, therefore they show strong affinity for the anions instead of cations and hence  
16 are permeable to anions. Thus the selectivity of polyurethane- $\text{Al}_2\text{O}_3$  anion exchange fibrous  
17 composite membrane results from the exclusion of cations (co-ions) from membrane phase and  
18 permits transfer of anions (counter ions). As the concentration of versatile anion is higher in the  
19 solution than membrane, the concentration gradients are created between the membrane and the  
20 solution. This gradient difference allows the versatile anions to move into the film. Due to  
21 electro neutrality conditions, the permeation of cations into the solution and anions into the  
22 membrane prompts a counter-acting charge because of uncompensated ions and equilibrium is

1 created between the attempts of diffusion on one side and the establishment of an electrical  
2 potential difference on the other. Thus electrical potential difference between polyurethane-  
3 Al<sub>2</sub>O<sub>3</sub> anion exchange fibrous composite membrane and adjacent salt solution can be measured.

4 In the preliminary tests, polyurethane-Al<sub>2</sub>O<sub>3</sub> membrane electrode indicated stable potential  
5 responses in solutions containing dichromate ion while all other anions show negligible potential  
6 responses in the concentration ranging from  $1 \times 10^{-1}$  mol L<sup>-1</sup> and  $1 \times 10^{-8}$  mol L<sup>-1</sup>. In this manner,  
7 the detailed performance of the membrane electrode, in aqueous solutions containing dichromate  
8 ion was studied.

#### 9 ***4.6. Potentiometric Selectivity***

10 The selectivity is one of the important characters of the ion-selective electrodes, determining  
11 whether reliable measurement in the target sample is possible or not. The selectivity was  
12 determined by the mixed solution method (MSM) and is evident from Table 3. Most of the  
13 interfering ions showed low values of selectivity coefficient, indicating no interference in the  
14 performance of the membrane electrode assembly. Such high selectivity of the proposed ion-  
15 selective electrode over other ions reflects high affinity of the membrane towards the Cr(VI)  
16 ions.

#### 17 ***4.7. Performance of Cr(VI) selective electrode***

##### 18 ***4.7.1. Working concentration range and slope***

19 Polyurethane-Al<sub>2</sub>O<sub>3</sub> anion exchange fibrous composite membrane based Cr(VI) ion-selective  
20 electrode gave a linear relationship between electrode potential and the negative logarithm of  
21 Cr(VI) concentration ranging from  $1 \times 10^{-1}$  to  $1 \times 10^{-8}$  mol L<sup>-1</sup>. Suitable concentrations were

1 chosen for sloping portion of the linear curve. The limit of detection (LOD) was determined from  
2 the intersection of the two extrapolated segments of the calibration graph [32] was found to be  $1$   
3  $\times 10^{-9}$  mol L<sup>-1</sup>, thus it can be concluded that the working concentration range is  $1 \times 10^{-1}$  to  $1 \times 10^{-$   
4  $8$  mol L<sup>-1</sup> (Fig. 5) for Cr(VI) ions with a slope of 30.36 mV/decade for the calibration curve.

#### 5 *4.7.2. Effect of pH on electrode potential and response time*

6 The pH effect on the potential response of the electrode was measured for  $1 \times 10^{-5}$  mol L<sup>-1</sup> of  
7 Cr(VI) ion concentration at different pH values. The pH of the solution was adjusted with HCl  
8 and NaOH. From Fig.6 it can be seen that the pH dependence on the potential is insignificant in  
9 the pH range of 2.0-4.0 which can be taken as working pH range for the electrode. Another  
10 important factor is the promptness of the response of the ion-selective electrode and the average  
11 response time is defined as the time required for the electrode to reach a stable potential. The  
12 response time of the membrane in contact with  $1 \times 10^{-5}$  mol L<sup>-1</sup> Cr(VI) was found to be ~20 s  
13 which is evident from the Fig.7. The shelf life was also measured and it was found that the  
14 membrane could be successfully used up to 12 months without any notable drift in potential  
15 during which the potential slope is reproducible within  $\pm 1$  mV per concentration decade.  
16 Whenever a drift in the potential was observed, the membrane was re-equilibrated with 0.1 mol  
17 L<sup>-1</sup> potassium dichromate solutions for 3-4 days.

#### 18 *4.7.3. Accuracy*

19 The ion selective membrane electrode was found to work well under laboratory conditions. In  
20 order to evaluate the accuracy, an Cr(VI) selective electrode was applied for the determination of  
21 arsenate in various samples of drinking water containing different amount of Cr(VI), ranging  
22 from 5 to 20 mg L<sup>-1</sup>. Each sample was analyzed in triplicate by membrane electrode and results

1 were tested by standard addition method. The results given in Table 4 show that the amount of  
2 Cr(VI) recovered with the help of the membrane electrode is in good agreement with that  
3 determined by AAS, thereby reflecting the high accuracy as well as utility of the proposed  
4 method.

5 Table 5 shows the comparative working concentration range, response time, life time, pH range  
6 and detection limit of the proposed electrode in comparison to other reported Cr(VI) ion-  
7 selective electrode [33-35]. The results clearly indicated the superiority of the proposed electrode  
8 in terms of linear range, pH, response behavior and detection limit.

9 The traditional plasticized PVC membrane with no carrier showed inconsequential selectivity  
10 towards dichromate ion and its response was not reliable as shown by Benvidi et al. [36], while,  
11 polyurethane- $\text{Al}_2\text{O}_3$  membrane exhibited Nernstian response and had discernible selectivity for  
12 dichromate ion compared with the other anions.

### 13 **5. Conclusion**

14 In the present paper, new and novel polyurethane- $\text{Al}_2\text{O}_3$  anion exchange fibrous composite  
15 containing different amount of  $\text{Al}_2\text{O}_3$  were prepared by using a simple chemical route. The  
16 obtained results show that the composite fibers have good ion-exchange capacity, thermal  
17 stability and its Cr(VI) selective membrane electrode has good operating characteristics,  
18 including Nernstian response, reasonable detection limit, relatively high selectivity, wide  
19 dynamic range and fast response. These characteristics and the typical applications presented in  
20 this work make the sensor a suitable one for measuring Cr(VI) content in real samples without a  
21 significant interaction from anionic species. It may be suggested that polyurethane- $\text{Al}_2\text{O}_3$  fibrous

1 composite can be used as a new sensing material for detection of Cr(VI) from water and  
2 wastewater. Beside these polyurethane- $\text{Al}_2\text{O}_3$  fibrous composite may find practical applications  
3 as potential adsorbent for removal of Cr(VI) from water and wastewater.

Graphical Abstract

Ion-selective electrode was developed by using polyurethane- $\text{Al}_2\text{O}_3$  organic-inorganic fibrous composite for the determination of Cr(VI) from water.
