⁵ *Received (in XXX, XXX) Xth XXXXXXXXX 20XX, Accepted Xth XXXXXXXXX 20XX* **DOI: 10.1039/b000000x**

Hollow In₂O₃ microspheres constructed by primary nanoparticles were successfully prepared by thermal treatment of the precursor, which was synthesized via a facile chemical solution route without any templates or surfactants. The images of field emission scanning electron microscopy (FESEM) and

¹⁰ transmission electron microscopy (TEM) indicated that the sample was composed of a large number of hollow In₂O₃ microspheres with diameters of 1-2 μ m. In addition, gas sensor based on the In₂O₃ hollow microspheres was fabricated and its gas sensing performances were investigated. It was found that sensors based on the as-prepared sample had a low operating temperature (80°C), and exhibited high response, low detection limit and excellent selectivity to $NO₂$.

¹⁵ **1. Introduction**

In the past decade, the investigation of oxide semiconductor for gas sensing applications has become hot topic because of an increasing concern on the safety in environment and industrial activities.^{[1-3](#page-6-0)} For oxide semiconductor gas sensors, high sensitivity ²⁰ and excellent selectivity are the two most important parameters.

- Therefore, developing new strategies for increasing sensitivity and improving selectivity of sensors represent one of the major scientific challenges. A critical element in the pursuit of this quest is the discovery of efficient and cost-effective sensing
- ²⁵ materials. Due to well-defined interior voids, good surface permeability, low density, and high specific surface area, hollow structural sensing materials have attracted growing interest in recent years.^{[4-9](#page-6-1)} Generally, the syntheses depend on complicated templating approaches,^{[9-11](#page-6-2)} in which hard or soft sacrificial ³⁰ templates are used to create a hollow structure. However,
- template contamination mostly decreases the activity of sensing materials and the synthetic procedure is tedious and high cost. In this regard, it is still highly desirable to develop facile, solutionbased, and template free self-assembly methods for the ³⁵ preparation of hollow structures.

Indium oxide (In_2O_3) is a very important wide-band-gap (Eg $= 3.6$ eV) n-type semiconductor, well-known for its useful optoelectronic properties.^{[12-14](#page-6-3)} In₂O₃ nanostructures can be synthesized via various methods and have found use in a variety

- $\frac{1}{40}$ of electronics applications.^{[15-17](#page-6-4)} They are also of some interest as gas sensors, which have been found to be particularly sensitive to reducing gases^{18, [19](#page-6-6)} such as ethanol and oxidizing gases^{20, [21](#page-7-0)} such as nitrogen dioxide and ozone. Many studies have been conducted in order to improve the performance of gas sensors by
- 45 reducing the size of In₂O₃ since Yamazoe demonstrated that a reduction in crystallite size could significantly enhance sensing performance.^{[22,](#page-7-1) [23](#page-7-2)} However, the aggregation between the

nanoparticles will result in the degradation of the gas sensing properties. Recently, In_2O_3 with hollow structures have been ⁵⁰ demonstrated to be promising candidates for ultrasensitive sensors due to their unique structures, which are conducive to the diffusion and recognition of gas. 24 24 24 Herein, a one-step templatefree solvothermal approach is reported for the synthesis of In_2O_3 hollow microspheres. When evaluated as the sensing material for 55 gas sensor, the as-prepared $In₂O₃$ hollow microspheres

manifested high response and excellent selectivity to $NO₂$ at a relatively low temperature (80 °C).

2. Experimental

2.1 Synthesis of In2O3 hollow microspheres

All the reagents in the experiment were purchased from Sinopharm Group Co. Ltd., and directly used without further purification. In a typical synthesis process, 0.26g of In(NO₃)₃ \cdot 4.5H₂O and 0.5 g of urea were added to 40 mL absolute ethanol under vigorous stirring. After 40 min stirring, the mixture ⁶⁵ was transferred into a Teflon-lined stainless-steel autoclave and maintained at 160 °C for 12 h. After the autoclave was cooled to room temperature naturally, the precipitates were washed with deionized water and absolute ethanol for several times using centrifuge, and then dried at 80 °C. The obtained product was 70 then calcined at 500 °C for 2 h in an air atmosphere using a muffle furnace.

2.2 Characterization

X-ray diffraction (XRD) patterns were recorded on a Rigaku D/Max-2550V X-ray diffractometer with Cu-K α radiation (λ = ⁷⁵ 1.5406Å) to analyze the crystal phases of the synthesized samples. The morphology of the product was examined by field emission scanning electron microscopy (FESEM, JEOL JSM-7500F

microscope operated at an acceleration voltage of 15 kV). Transmission electron microscopic (TEM), high-resolution transmission electron microscopic (HRTEM), and the corresponding selected-area electron diffraction (SAED) ⁵ measurements were performed on a JEOL JEM-2100F

transmission electron microscope with an acceleration voltage of 200 kV.

2.3. Fabrication and measurement of gas sensors

- ¹⁰ The as-prepared powder was mixed with deionized water to make a paste, which was then coated onto an alumina tube (4 mm in length, 1.2 mm in external diameter, and 0.8 mm in internal diameter, attached with a pair of gold electrodes) by a small brush to form a thick film. The thickness of sensing films was about
- ¹⁵ 100 μm. After drying at room temperature for 30 min, the sensing devices were sintered at 400 °C for 2 h. A Ni-Cr heating wire was used to adjusting the operating temperature of the sensor. Finally, the sensor was constructed by connecting the corresponding junctions to the socket of sensor. A photo of the fabricated sensor
- ²⁰ was presented in Fig.1, and the corresponding parts of the sensor were marked in this figure. The measurement was processed by a static process in a test chamber which is made of glass. Environmental air was used as both a reference gas and a diluting gas to obtain desired concentrations of target gases. A given
- ²⁵ amount of the tested gas was injected into the test chamber, and the sensor was put into the chamber for the measurement of the sensing performance. When the response reached a constant value, the upper cover of the test chamber was removed and the sensor began to recover in air. The response of the sensor was defined as
- 30 R_{ϱ}/R_{α} for oxidizing gas and R_{α}/R_{ϱ} for reduction gas, here R_{ϱ} and R_a were the resistances of the sensor in the target gas and air, respectively. The response and recovery times are defined as the time taken by the sensor to achieve 90% of the total resistance change in the case of adsorption and desorption, respectively.

³⁵ **3. Results and discussion**

3.1 Structural and morphological characteristics

The typical XRD pattern of the sample is shown in Fig. 2, from which all the diffraction peaks could be very well indexed to the cubic structure of In_2O_3 with the lattice parameter of

Fig. 1 Photograph of the fabricated sensor.

Fig. 2 XRD pattern of the In_2O_3 hollow microspheres and the standard 45 XRD pattern of In_2O_3 (JCPDS No. 06-416).

 $a=10.118$ Å, which were in good consistent with the standard file JCPDS No. 06-416 and the diffraction peaks in the XRD pattern are of high relative intensity, indicating the high crystallinity and high purity of the samples. The mean crystallite size of In_2O_3 was ⁵⁰ calculated to be around 16.6 nm using the Debye-Scherrer equation (D=0.89 λ /(βcosθ)).

Field emission scanning electron microscopy (FESEM) observations were carried out to get insight into the morphology of In_2O_3 products. Fig. 3 presents a panoramic FESEM image of 55 the In₂O₃ sample, which indicates that it was composed of spherical structures with sizes ranging from 1-2 μm. The hollow interior space can be clearly observed from the enlarged FESEM image of cracked microsphere (the inset of Fig.3). Furthermore, numerous primary particles with size of tens of nanometres piled ⁶⁰ up the hollow structure.

Further detailed morphological and structural analysis of the hollow microsphere was carried out using TEM, HRTEM and the corresponding SAED. The hollow nature of the In_2O_3 spheres could be further confirmed in the strong contrast between the ⁶⁵ dark edge and pale centre in the TEM image of an individual sphere (Fig. 4a), and it can be also observed that nanoparticles

Fig. 3 A panoramic FESEM image of the In_2O_3 sample. The inset shows a ⁷⁰ cracked microsphere.

Fig. 4 (a) TEM image, (b) SEAD pattern and (c) HRTEM image of the calcined product (12h).

constructed the hollow spheres. The corresponding SAED pattern 5 (Fig. 4b) demonstrated that the In₂O₃ hollow microspheres were polycrystalline structures in nature. Fig. 4c exhibits the HRTEM image obtained from the marked fringe of the In_2O_3 nanoparticles in Fig. 4a, from which the lattice fringes could be clearly observed and the distance of the adjacent lattice planes was ¹⁰ measured to be 0.295 nm, corresponding to the (222) planes of In_2O_3

To understand the formation process of the hollow In_2O_3 microspheres, a series experiments were carried out at different reaction time (2 h, 8 h, and 12 h), and the evolutions of structure ¹⁵ and morphologies of the calcined samples were examined by

- FESEM. As shown in Fig. 5, the growth process could be clearly divided into three stages. In the first stage (2 h, Fig.5a), solid spherical structures with very rough surface that composed of nanoparticles and nanosheets could be observed. With increasing
- ²⁰ reaction time (8h, Fig.5b), the surface of the spheres became less rough and the hollow characteristic emerged, which is the typical behaviour of ripening process. Upon prolonging reaction time to 12 h (Fig.5c), microspheres with hollow internal structure and rough surface were obtained. In general, the formation process
- ²⁵ could be summarized as a rapid self-assembly of nanosheets and nanoparticles into solid microspheres, followed by the component part that packed at the centre dissolved and transferred to the exterior. Based on the above analysis, Ostwald ripening process could be employed to explain the growth process. [25-27](#page-7-4)

3.2 Gas sensing properties

The gas sensing performances of the sensor using hollow

Fig. 6 (a) The dynamic response resistances of the fabricated sensor to 500ppb NO2 at 40 °C, 60 °C, 80 °C, 100 °C and 120 °C . (b) The correlation of the response with the operation temperature. And (inset of b) the correlation of the response/recover time with the operation ⁴⁰ temperature.

 In_2O_3 microspheres were investigated. It is well known that the gas-sensing properties of a semiconductor gas sensor are significantly influenced by the operation temperature. [28](#page-7-5) Because the adsorption/desorption processes and the competition for 45 chemisorptions between NO₂ and atmospheric oxygen O₂ for the same active surface sites chemisorptions are both regulated by the temperature.[29](#page-7-6) To find out the influence of the temperature to the

35

fabricated sensor, the response, response time and recovery time towards 500 ppb $NO₂$ were tested at varying operation temperature, as shown in Fig. 6. It is obvious that the response to NO2 increased with the decrease of temperature, and the

- 5 fabricated sensor exhibited excellent response to $NO₂$ at relatively low temperature. The response to 500 ppb NO₂ at 120 °C, 100 °C, 80 °C, 60 °C and 40 °C were about 47.5, 193.7, 323.5, 674.1 and 879.9, respectively. So the fabricated sensor could operate at relatively low temperature, which meant low power consumption
- ¹⁰ and this was very important for a gas sensor to be put into use. Apart from response, response time and recovery time also need to be considered to comprehensive measure the gas sensing performance of a gas sensor. The correlation of the response time and recovery time with the operation temperature were presented
- ¹⁵ in the inset of Fig.6b. As can be seen, the response time and recovery time also increased with the decrease of temperature. Roughly speaking, with the decrease of the temperature, the gas molecules became less and less active which led to the increase of the response time and recovery time. But the decrease of the
- ²⁰ temperature would also make the gas adsorption easier and the depth of gas diffusion deeper which will cause the high utilization rate of the sensing material, thus leading to higher response. $30-34$ Moreover, when the temperature was higher than 80 °C, the change of temperature had not obvious effects on the response
- ²⁵ time and recovery time. Therefore, although the response to 500 ppb $NO₂$ at 80 °C (323.5) was not the highest, considering response time and recovery time, 80 °C was chosen to be the optimal operation temperature of the fabricated sensor for $NO₂$ detection, which was employed to further investigate the sensing ³⁰ performances.

The relationship between response and $NO₂$ concentrations for the sensor at the operating temperature of 80 \degree C is displayed in Fig. 7a. From the curve, it is found that the responses of sensor increased with the gas concentration. The response to 50, 100,

- ³⁵ 200, 300, 400 and 500 ppb NO2 were about 2.0, 3.1, 6.1, 39.1, 119.8 and 323.5, respectively. It is worth noting that the sensor showed an obvious response (2.0) even to $NO₂$ concentration as low as 50 ppb, which indicated that the sensor had a relatively low detection limit (shown in the inset of Fig. 7a). A comparison
- ⁴⁰ between the sensing performances of the sensor presented in this paper and literature reports is summarized in Table 1. It is noteworthy that the sensor fabricated in our work exhibits better sensing performance compared with those reported in the literature.
- ⁴⁵ Except for response, response time and recovery time, selectivity is also an important parameter for gas sensor. Eight kinds of other gases were tested, including 100 ppm NO, NH₃, CO, methanol, methanol, ethanol and acetone, 50 ppm SO_2 , and 500 ppb O_3 . The test results are presented in Fig.7b. It is clear
- 50 that the fabricated sensor exhibits the highest response to $NO₂$ among all these tested gases, and the response to 500 ppb $NO₂$ was at least dozens of times higher than the other tested gases at the optimum operation temperature (80 $^{\circ}$ C). The test results indicated that the gas sensor based on the hollow microspheres 55 In₂O₃ possess an excellent selectivity to NO₂ against the other test gases.

The responses of the fabricated sensor to 500 ppb $NO₂$ under different relative humidity at 80 °C were also tested to find out the effect of the humidity on the response of the sensor. And the ⁶⁰ results were presented in Fig 7.c. The results indicated that the

Fig. 7 (a) Response of the sensor versus $NO₂$ concentrations in the range of 50-500 ppb at 80 °C. (b) Response of the sensor to various test gases at 80 °C. (c) Response of the sensor to 500 ppb $NO₂$ under different relative 65 humidity at 80 °C.

response decreased with the rise of relative humidity almost linearly. According to D. Vlachos et al.³⁵, the decrease might be caused by the active sites on the material surface were covered gradually by water molecules.

The most widely accept sensing mechanism of the sensor based on In_2O_3 to NO_2 gas can be stated as follow. ^{[36-42](#page-7-8)} The electrical conductivity of In_2O_3 derives from electron transfer Table 1 Comparison of gas-sensing characteristics of sensing material in present work and those reported in the literatures.

between In²⁺ and In³⁺, the formation of the In²⁺ occurring through oxygen deficiency (Eq.(1)). Anion vacancies V_0 • and mainly

- partially reduced cations In²⁺ are the surface basic sites (S_b) _s for NO2 chemisorption. And the formation of the chemisorption bond continued on the charge transfer from active sites (S_b) _s into an orbital of $NO₂$ causes a reduction in the strength of N-O bonds that makes the decomposition of the $NO₂$ molecules easier.
- 10 Therefore, NO_2 molecules were reduced into NO or N_2 and the electronics of the In_2O_3 sensing materials were captured which led to the increase of the resistance of the sensor. The sensing mechanism could be summarized according to the following equations.

$$
\text{is } \text{In}_2\text{O}_3 \to \text{In}_{2-x}^{3+} \text{In}_{x}^{2+} \text{O}_{3-x} \text{V}_{0x}^* + \frac{1}{2} \text{O}_2 \tag{1}
$$

$$
NO_{2,gas} + In^{2+} \rightarrow (In^{2+} - NO_{2,ads}) \rightarrow (In^{3+} - O_{ads}^-) + NO_{gas} \tag{2}
$$

$$
NO_{gas} + In^{2+} \rightarrow (In^{2+} - NO_{ads}) \rightarrow (In^{3+} - O_{ads}^+) + \frac{1}{2}N_2
$$
 (3)

$$
{}_{20}NO_{2,gas} + V_o^{\bullet} \rightarrow (V_o - NO_{2,ads}^{-}) \rightarrow (V_o - O_{ads}^{-}) + NO_{gas}
$$
 (4)

$$
NO_{gas} + V_o^{\bullet} \rightarrow (V_o - NO_{ads}^{\dagger}) \rightarrow (V_o - O_{ads}^{\dagger}) + \frac{1}{2}N_2
$$
 (5)

4. Conclusions

In summary, hollow In_2O_3 microspheres had been successfully synthesized by a simple solvothermal method and ²⁵ subsequent annealing process. FESEM and TEM images displayed that the microspheres were composed of nano-sized primary particles. Moreover, gas sensors based on the as-obtained hollow microspheres were fabricated and their sensing performances were investigated. It was found that the sensor ³⁰ exhibited high response, low detection limit and excellent selectivity to $NO₂$ at a low operating temperature (80 $^{\circ}$ C).
