A series of Dy^{3+}/K^+ doped calcium molybdate phosphors were synthesized by hydrothermal synthesis method and the structural, photoluminescence and decay studies were carried out. Crystal structure and phase of the prepared phosphors were investigated using X-ray diffraction (XRD), Transmission electron microscopy (TEM) and Fourier transform infrared spectroscopy (FTIR). These studies show that the phosphors are of tetragonal structure with nanorod morphology. The photoluminescence results indicate that these phosphors could be efficiently excited by the near-ultraviolet radiation which causes the emission in the blue and yellow regions. A novel approach was used to calculate different spectral parameters of powder samples using excitation spectra instead of conventional absorption spectra. Quantitative calculation of spectral parameters, luminescence decay and quantum yield suggest the suitability of this phosphor as efficient luminescent media for light emitting devices.

20 1. Introduction

Study of optical spectra of rare-earth (RE) ions doped phosphors has been an active area of research due to their wide application in solid-state lasers, lighting and display devices ^{1,2}. As an effective laser/ luminescent media Calcium Molybdate, CaMoO₄ is a ²⁵ promising host candidate for properties such as high melting point (1445–1480°C), high refractive index (1.98), average decay time (14 ms), quantum yield (9%), absorption cross section (~10³ cm⁻¹) ³. Therefore, luminescence properties of different rare earth doped CaMoO₄ phosphor have been studied previously to achieve a good ³⁰ luminescent media ⁴⁻⁷.

The performance of luminescent materials can be assessed by the knowledge of Judd–Ofelt (JO) intensity parameters Ω_t (t = 2, 4, 6), spontaneous emission probabilities, oscillator strength and radiative branching ratios. The Ω_2 parameter is associated with the ³⁵ polarization and asymmetry of the RE ligands. The other two parameters $\Omega_{4,6}$ depend on long range effects. However, it is very difficult to calculate the JO intensity parameters for powder

materials since the quantitative absorption spectra of powder materials can hardly be measured especially for the case of low RE 40 dopant concentration. Now a days, with the development of novel nanophosphors for various display and lighting applications, it is very much required to find more convenient methods for the determination of JO intensity parameters in case of powder materials, which are essential to predict RE spectral properties for a ⁴⁵ variety of material applications. An approach simply based on the measurement of the excitation spectra has been proposed by W Luo et al. to determine the JO parameters for RE³⁺ ions doped powders ⁸. The approach has been successfully applied to three systems: NGW:Er, YLF:Nd and Y₂O₃:Er³⁺ nanocrystals and the ⁵⁰ obtained JO parameters using this approach were in good agreement with that determined from the conventional method.

As per our literature survey till date no work has been reported on the estimation of JO parameters of doped /codoped CaMoO₄ phosphors. The authors have already reported the luminescence ⁵⁵ properties of this K⁺ compensated Dy³⁺ doped CaMoO₄ phosphors ⁹. Keeping this in view, an attempt was made for the first time to estimate different spectral parameters, luminescence decay time and quantum yield of the optimized Dy³⁺ doped and K⁺ compensated codoped phosphor from the excitation spectra.

60 2. Experimental

2.1. Sample synthesis

Doped Ca_{1-x}MoO₄: Dy_x³⁺ (x = 0, 0.01, 0.015, 0.02, 0.03, 0.04, 0.05) phosphors and codoped Ca_{1-x-y}MoO₄: Dy_x³⁺ K_y⁺ (x= 0.02, y = 0.01,

0.02, 0.03, 0.04, 0.05) phosphors were prepared by hydrothermal synthesis. The reactants CaCO₃, (NH₄)₆Mo₇O₂₄.4H₂O, Dy₂O₃ and K₂CO₃ were weighted in an appropriate stoichiometric ratio. All reagents were analytical grade and used without further

- 5 purification. In a typical synthesis, solution A was prepared by dissolving CaCO₃ and Dy₂O₃ in diluted nitric acid. The solution was heated to drive away the unreacted nitric acid, and the residue was redissolved in 10 mL of deionized water and stirred for about 1hour at room temperature. (NH₄)₆Mo₇O₂₄.4H₂O was dissolved in
- 10 50 mL of deionized water named solution B. After stirring for about 15 minutes, solution B was added dropwise into the solution A under vigorous stirring. The pH of the solution was adjusted in between 8-9 using NaOH solution (1N). The resulting precursor solution was further stirred for about half an hour. After that, the
- 15 solution was poured into 80-mL capacity Teflon-lined stainless steel autoclave and further heated to 180°C for 12 hours. After cooling down to room temperature naturally, the nanophosphors were directly collected at the bottom of the vessel. The phosphors were filtered, washed several times with deionized water and
- ²⁰ absolute ethanol, and dried in oven at100 °C for 5 hours ¹⁰. For the preparation of codoped phosphors, solution A was prepared by dissolving CaCO₃, Dy₂O₃ and K₂CO₃ in diluted nitric acid and rest of the procedure was same.

2.2. Sample characterization

- 25 X-Ray diffractogram of the prepared phosphors were recorded in a wide range of Bragg angle 2θ ($10^{\circ} \le 2\theta \le 80^{\circ}$) using Bruker D8 X-Ray diffractometer with CuK_a radiation ($\lambda = 0.154056$ nm). FTIR studies were carried out on Perkin Elmer make Spectrum RX1 Spectrometer. Morphology and crystallite size of the phosphors
- 30 were determined by JEOL make JEM-2100 transmission electron Microscope. Photoluminescence studies were carried out on Hitachi make F-2500 Fluorescence Spectrophotometer in the wavelength range 220 nm - 700 nm. The decay kinetics was studied on Quanta Master 40 fluorometer. All the studies were 35 carried out at room temperature.

2.3. THEORITICAL BACKGROUND

2.3.1. Judd-Ofelt theory

The J-O theory ^{11,12} has been extensively used to analyze the radiative transitions of rare-earth ions in several host materials. The 40 electric-dipole (ED) and magnetic-dipole (MD) transitions are mainly used to calculate the line strengths of optical spectra of RE³⁺ ions in luminescent materials. For most of the transitions, the probability for magnetic dipole transitions is much smaller than those for the forced electric dipole transitions ⁴⁵ $[A_{md}[J \rightarrow J'] < A_{ed}[J \rightarrow J']$. However, in certain cases, they may significantly contribute to the total $J \rightarrow J'$ radiative transition probability.

The excitation line strength for an ED transition can be expressed in terms of J-O intensity parameters $\Omega_{2, 4, 6}$ by

$$\int_{calc}^{S_{calc}^{ad}} (J \to J') = \sum_{t=2,4,6} |Q_t| |Q^t| |Q^t| |\phi J'\rangle|^2$$
(1)

where the matrix elements $\langle || U^{(t)} || \rangle$ are doubly reduced unit tensor operator ¹³ of rank t calculated in the intermediate coupling approximation and are independent of the crystal host. The parameters Ω_2 , Ω_4 , and Ω_6 exhibit the influence of the host on the 55 transition probabilities since they contain the crystal-field parameters, inter configurational radial integrals, and the interaction between the central ion and intermediate environment. The reduced matrix elements of the unit tensor $|\langle \varphi J || U' || \varphi' J' \rangle|^2$ were taken from ref. 14.

60 The measured line strengths (S_{meas}^{ed}) were calculated from the excitation spectrum by:

$$S_{meas}^{ed}(J \to J') = \frac{3ch(2J+1)}{8\pi^3 \,\overline{\lambda} e^2 N_0} \frac{9n}{(n^2+2)^2} \Gamma_{exc}$$
(2)

where J (J') is the angular momentum quantum number of the initial (final) state of rare earth ion, n is the refractive index of the sample, λ is the mean wavelength of the excitation band, N₀ is rare earth ion concentration and Γ_{exc} is the integrated excitation intensity for each band from the initial state to the final state which is similar to the integrated absorbance for the absorption spectrum ⁸. The factor $[9n/n^2+2]^2$ in Eq. 2 is the local field correction for the 70 ion in the dielectric host medium. The measured line strengths were then used to obtain the J-O parameters Ω_2 , Ω_4 , and Ω_6 by solving a set of n number of equations for the corresponding transitions between J and J'. A least squares fit method was used for Eqns. (1) and (2) to get a good fit between the calculated and 75 measured line strengths as well as to obtain J-O intensity parameters (Ω_t).

The magnetic-dipole transitions are parity allowed between states of the $4f^{\mathbb{N}}$ configuration and are subject to the selection rules, $\Delta I=0$, $\Delta S=0$, $\Delta L=0$, $|\Delta J| \le 1$, (but not $0 \leftrightarrow 0$) in the Russel – Saunders ⁸⁰ limit ¹⁵. The line strengths due to the magnetic dipole contribution were determined using the following expression:

$$S_{calc}^{md}(J \to J') = \left(\frac{eh}{4\pi mc}\right)^2 |\langle (SLJ) || L + 2S || \langle S'L'J' \rangle|^2$$
(3)

The line strengths of the bands due to magnetic dipole transition are determined from the corresponding values of oscillator ss strengths, f_{calc}^{md} using the following expression:

$$S_{calc}^{md}(J \to J') = \frac{3h(2J+1)n^2}{8\pi^2 m c \nu} f_{calc}^{md}$$
 (4)

Values of f_{calc}^{md} were taken from Carnall et al ¹⁶.

2.3.2. Radiative properties

The J-O parameters were used to predict the radiative properties of

2 | Journal Name, [year], [vol], oo-oo

This journal is © The Royal Society of Chemistry [year]

the excited states of Dy^{3^+} ion. The radiative transition probability (A_R) for a transition $J \rightarrow J'$ is calculated from the following equation ¹⁷:

$$A_{R}(J \to J') = \frac{64\pi^{4}v^{3}}{3h(2J+1)} \left[\frac{n(n^{2}+2)^{2}}{9} S_{ed} + n^{3}S_{md} \right]$$
(5)

s where S_{ed} and S_{md} are the electric and magnetic-dipole linestrengths. The radiative lifetime (τ_R) of an excited state is given by

$$\tau_{R}(J) = \frac{1}{\sum_{\psi'J'} A_{R}(J \to J')} \tag{6}$$

The branching ratio (β_R) corresponding to the emission from an excited level J to lower level J' is given by

$$_{0}\beta_{R}(J,J') = \frac{A_{R}(J \to J')}{\sum_{J'}A_{R}(J \to J')}$$

$$\tag{7}$$

The stimulated emission cross-section ($\sigma(\lambda_p)$) can be expressed as:

$$\sigma(\lambda_p)(J \to J') = \frac{\lambda_p^4}{8\pi c n^2 \Delta \lambda_{eff}} A_R(J \to J')$$
(8)

where λ_p is the peak wavelength and $\Delta \lambda_{eff}$ is its effective linewidth found by dividing the area of the emission band by its maximum ¹⁵ height.

3. Results and Discussions

3.1. Structural analysis

3.1.1. XRD studies:

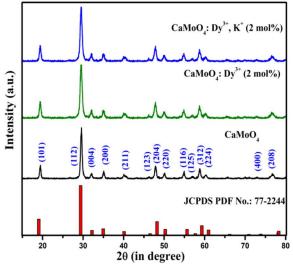

Figure 1. XRD spectra of CaMoO₄ phosphors.

²⁰ Figure 1. shows the XRD spectra of undoped CaMoO₄, 2 mol% Dy³⁺ doped CaMoO₄ and 2 mol % K⁺ codoped CaMoO₄ phosphors. A single tetragonal phase was observed and diffraction peaks match with *JCPDS* card no 77-2244 with space group I4₁/a (88).

This journal is © The Royal Society of Chemistry [year]

The substitution of Dy^{3+} and K^+ for Ca^{2+} did not influence the phase ²⁵ and crystal structure of CaMoO₄ suggesting that dopant and codopant might have occupied the cationic sites in the host lattice structure, following the charge balancing ¹⁸: $2Ca^{2+} = Dy^{3+} + K^+$. The enhancement of XRD peak intensities in codoped phosphor is due to the incorporation of K^+ thus improving the crystallinity. The ³⁰ (h k l) values of most prominent peaks are shown in the XRD pattern.

3.1.2 Rietveld refinement:

A structural refinement by the Rietveld method ¹⁹ was performed using the Fullprof Program ²⁰. Figure 2a. shows the Rietveld plot for ³⁵ undoped CaMoO₄. The structural refinement results are presented in Table 1. Figure 2b. shows the schematic representation of the tetragonal CaMoO₄ unit cell. The unit cell was modelled through a program called Visualization for Electronic and Structural Analysis (VESTA) ²¹ using Rietveld refinement data. The Ca and Mo sites have ⁴⁰ S4 point symmetry. Its crystal structure has two building blocks of CaO₈ clusters with scalenohedral configuration and snub dispenoide polyhedra (8 vertices, 12 faces, and 18 edges) and MoO₄ tetrahedra. Due to the O-Mo-O bond angles, the [MoO₄] clusters are slightly distorted into the matrix ²². Each O atom links with two Ca atoms and ⁴⁵ one Mo atom. There are two different Ca–O bond lengths in CaO₈ and one Mo–O bond length in MoO₄.

Table 1: Structural parameters of undoped CaMoO₄ after Rietveld refinement.

Atoms	Wyckoff	x	у	Ζ	Occupancy	Lattice consta
Ca	4b	0	0.25	0.625	0.250	a = b = 5.12
Мо	4a	0	0.25	0.125	0.250	c = 11.11
0	16a	0.090	0.398	0.306	1.000	

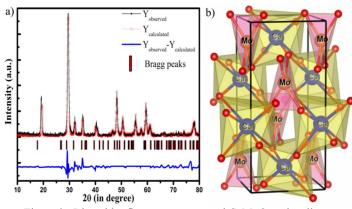

Figure 2. Rietveld refinement pattern and CaMoO₄ unit cell.

50 3.1.3. TEM Studies

TEM images of undoped $CaMoO_4$ phosphor is shown in Figure 3a. Nanorod like structures of 20 nm diameter was observed. The high resolution TEM (HRTEM) image suggests that phosphor is crystalline (Figure 3b). Its selected area electron diffraction (SAED) is shown in

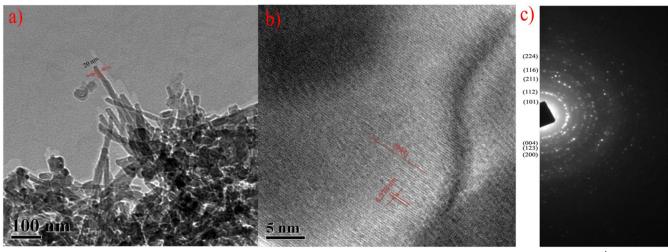

Figure 3. TEM studies of CaMoO₄ phosphor

Figure 3c. Based on a tetragonal phase, the rings are observed and (*hkl*) planes are indexed. The SAED pattern show the (101), (112), (004), (200), (123), (211), (116) and (224) planes in good agreement s with the XRD result. The lattice fringe was observed and d = 2.78 Å, which matches with *hkl* = 004 plane of tetragonal phase.

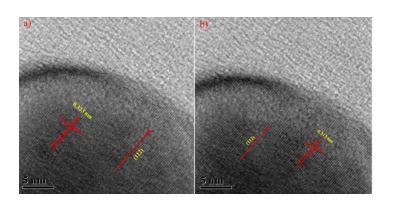

Figure 4. HRTEM studies of a) doped b) codoped CaMoO₄

phosphors.

¹⁰ Figure 4a and b show the HRTEM images of Dy^{3+} (2 mol %) doped³⁰ and Dy^{3+} , K⁺ (2 mol %) codoped phosphors. It clearly shows an improvement in crystallinity and d = 3.23 Å for doped and *d* = 3.13 Å for codoped phosphor, which matches with *hkl* = 112 plane.

3.1.4. FTIR Studies

- ¹⁵ FTIR spectra of the undoped, Dy^{3+} (2 mol %) doped, K⁺ (2 mol %) codoped phosphors in wave number range of 4000–400 cm⁻¹ are shown in Figure 5. It can be seen that all the phosphors show approximately similar vibrations. The strong absorption band occurring at 805 cm⁻¹ is due to the asymmetric stretching vibrations
- ²⁰ in the [MoO₄]²⁻ clusters and a weak band at 432 cm⁻¹ is due to the presence of asymmetric bending vibrations present in the O-Mo-O bonds ¹⁸. The inset illustrates a characteristic [MoO₄] cluster with asymmetric stretching and asymmetric bending vibrations between

the O-Mo-O bonds. The bands at 1652 and 3419 cm⁻¹ correspond to ²⁵ H–O–H bending and O–H stretching vibrations of water molecules ¹ present on the surface of particles respectively. The 1383 cm⁻¹ vibration is due to the N-O band of HNO₃ used during the preparation of sample. The peaks observed at 2382 and 2925 cm⁻¹ in the as-prepared sample indicates C–H stretching vibration ²³.

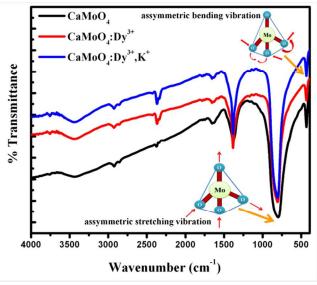

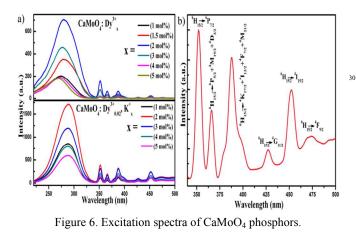

Figure 5. FTIR of CaMoO₄ phosphors.

3.2. Luminescence analysis

3.2.1. Excitation Spectra

The excitation spectra of Dy³⁺ doped CaMoO₄ with different Dy³⁺ ion concentrations (1, 1.5, 2, 3, 4 and 5 mol %) and K⁺ codoped CaMoO₄: ⁵ Dy with varying concentration of K⁺ (1, 2, 3, 4, 5 mol %) and optimum Dy³⁺ concentration at 2 mol % are shown in Figure 6a. The spectra exhibit a broad band from 220 nm to 330 nm with a maximum centred at 275 nm. This is due to charge transfer from oxygen (O²⁻) to metal (Mo⁶⁺) ion ²⁴. The other peaks ²⁵ at 351 nm (⁶H_{15/2}→⁶P_{7/2}), 366 ^o nm (⁶H_{15/2}→⁴M_{19/2}+⁴D_{3/2}+⁶P_{5/2}),387 nm (⁶H_{15/2}→⁴M_{21/2}+⁴K_{17/2}+⁴F_{7/2}+⁴I_{13/2}), 427 nm (⁶H_{15/2}→⁴G_{11/2}), 452 nm (⁶H_{15/2}→⁴I_{15/2}) and 475 nm (⁶H_{15/2}→⁴F_{9/2}) are due to f-f transition of

Dy³⁺. These transitions are magnified in Figure 6b.

3.2.2. J - O parameters

From the excitation spectra the measured line strengths (S_{meas}) ⁵ were determined by using Eq. (1). The Judd - Ofelt parameters Ω_2 , Ω_4 , Ω_6 were obtained using least-squares fitting approach between the S_{meas} and the S_{cal} . The J – O parameters, for various Dy^{3+} concentrations and for 2 mol% K⁺ codoped CaMoO₄ phosphors are tabulated in Table 2 along with the previously reported value for ¹⁰ CaMoO₄: Dy ²⁶.

Table 2: Judd-Ofelt intensity parameters

Phosphor	Mol %	Ω_2	Ω_4	Ω_6	$rms \square S$
		$\times 10^{-20}$	×10 ⁻²⁰	×10 ⁻²⁰	×10 ⁻²⁰
		(cm^2)	(cm^2)	(cm^2)	(cm^2)
CaMoO ₄ :Dy ³⁺ _x	x = 1	50.34	2.71	9.78	0.577
	x = 1.5	9.58	1.89	4.78	0.033
	x = 2	7.21	1.41	3.59	0.052
	x = 3	7.88	0.96	2.92	0.024
	x = 4	21.30	0.89	3.33	0.036
	x = 5	17.41	0.58	2.89	0.024
CaMoO ₄ :Dy ³⁺ _x ,K ⁺ _y	x = 2,	40.94	1.36	6.18	0.406
	y = 2				
CaMoO ₄ :Dy	1 wt %	0.266	2.89	1.79	
(from literature)					

There is not much variation of Ω_4 and Ω_6 with change in the Dy^{3+} concentration. But the experimental value of Ω_2 is most sensitive to the ligand environment which can be clearly observed by the ¹⁵ change of its value with concentration of Dy^{3+} and also with incorporation of K⁺ ions. Higher value of Ω_2 indicates high degree of metal-ligand covalency bond and lower symmetry of the coordination structure surrounding the Dy^{3+} ions ²⁷. The high Ω_2 value indicates the possession of high charge density for Dy^{3+} ion ²⁰ which polarizes the O²⁻ anion to a much greater extent. This result in a larger extent of molecular orbital overlap between the f orbital of the Dy^{3+} and the p orbital of the O²⁻ ion, resulting in expansion of the electron cloud and the formation of a bond having less ionic

and more covalent character. The decrease in Ω_2 value decreases ²⁵ orbital overlap between Dy^{3+} and O^{2-} and hence the covalent character ²⁸.

The root mean square (rms) deviation between the experimental and calculated line strengths is defined as:

$$rms\Delta S = \sqrt{\sum_{i=1}^{N} (S_{meas} - S_{cal})^2 / N - 3}$$
(9)

where N is the number of experimental bands involved in the above calculation. The value of the $rms\Delta S$ reflects the goodness of the J-O parameters fitting.

3.2.3 Emission Spectra

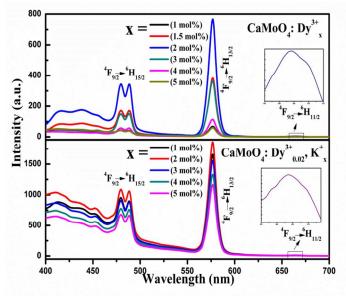

Figure 7. Emission spectra of doped and codoped CaMoO₄ phosphors.

Figure7. represents the emission spectra of doped/codoped CaMoO₄ phosphors as a function of Dy³⁺ and K⁺ concentration. Three peaks observed at 489, 576 and 663 nm is assigned to ⁴⁰ ⁴F_{9/2}→⁶H_{15/2} (blue), ⁶H_{13/2} (yellow) and ⁶H_{11/2} (red) transitions, respectively. The transition ⁴F_{9/2}→⁶H_{11/2} is of very low intensity which is magnified in the inset. The ⁴F_{9/2}→ ⁶H_{13/2} transitions are hypersensitive electronic dipole transitions with $\Delta J = 2$, which are greatly affected by the coordination environment and are allowed ⁴⁵ only at low symmetries with no inversion centre. In this case, the dominance of this transition indicates that the location of Dy³⁺ deviates from the inversion symmetry, i.e., at low symmetry positions. This also corroborates the fact that Ω_2 has a high value which implies the asymmetric coordination surrounding Dy³⁺ ions ⁵⁰ ^{18, 29}.

The luminescence intensity increases with increase of concentration of Dy^{3+} ions upto 2.0 mol % and then decreases. Quenching of luminescence with increasing Dy^{3+} ion concentration takes place as the distance between the neighboring Dy^{3+} ions decreases with the increase of Dy^{3+} ions. This decrease in the distance between the radiative transitions, thereby increasing the non-radiative energy transfer through cross relaxation channels. Keeping the Dy^{3+} concentration at 2 mol%, the

 K^+ mol concentration was varied from 1 to 5 mol% where the maximum intensity was recorded at 2 mol% of K^+ . This was due to the charge compensation phenomena as $2Ca^{2+} = Dy^{3+} + K^+$. This K^+ codoping increases the nonradiative decay paths for excited s Dy^{3+} which increases the emission intensity. But further increase in K^+ greater than 2 mol% increases the lattice distortion which reduces the emission intensity ⁹.

From the calculated J–O intensity parameters, the spectral parameters such as radiative transition probability (A_R), life-time ¹⁰ (τ_R) and branching ratio (β_R) were calculated. The emission spectra were used to calculate the parameters like peak emission wavelength (λ_p), effective line widths ($\Delta \lambda_{eff}$) and the peak emission cross-section ($\sigma(\lambda_p)$) using Eqs.(5) – (8). Experimental branching ratio (β_{exp}) was obtained by using the relative intensities of

¹⁵ individual peaks to that of the total intensity of emission peaks. All the spectral parameters including A_T and τ_R for the excited ${}^4F_{9/2}$ level are tabulated in Table 3.

Table 3: Spectral parameters

Transition β_{exp}		β_{cal}	A_R	$\sigma(\lambda_p)$			
${}^{4}F_{9/2} \rightarrow$			x10 ³	x 10 ⁻²⁰			
			(sec^{-1})	cm ²			
⁶ H _{15/2}	0.306	0.111	0.619	0.100			
⁶ H _{13/2}	0.691	0.844	4.6996	1.52			
⁶ H _{11/2}	0.031	0.045	0.2525	0.103			
$A_{\rm T} = 5.5711, \tau_{\rm R} = 179.5 \mu {\rm s}$							
⁶ H _{15/2}	0.355	0.093	0.7865	0.079			
⁶ H _{13/2}	0.631	1.015	8.6093	2.56			
${}^{6}\text{H}_{11/2}$	0.003	0.010	0.0869	0.029			
	$\begin{array}{c} {}^{4}F_{9/2} \rightarrow \\ \\ ^{6}H_{15/2} \\ {}^{6}H_{13/2} \\ {}^{6}H_{11/2} \\ \\ \hline \mu s \\ {}^{6}H_{15/2} \\ {}^{6}H_{13/2} \end{array}$	$\begin{array}{ccc} {}^{4}F_{9/2} \rightarrow & & \\ \\ \hline {}^{6}H_{15/2} & 0.306 \\ {}^{6}H_{13/2} & 0.691 \\ \hline {}^{6}H_{11/2} & 0.031 \\ \hline \mu s \\ {}^{6}H_{15/2} & 0.355 \\ {}^{6}H_{13/2} & 0.631 \\ \end{array}$	$\begin{array}{cccc} {}^{4}\mathrm{F}_{9/2} \rightarrow & & \\ & {}^{6}\mathrm{H}_{15/2} & 0.306 & 0.111 \\ {}^{6}\mathrm{H}_{13/2} & 0.691 & 0.844 \\ {}^{6}\mathrm{H}_{11/2} & 0.031 & 0.045 \\ \hline \mu \mathrm{s} & & \\ & {}^{6}\mathrm{H}_{15/2} & 0.355 & 0.093 \\ {}^{6}\mathrm{H}_{13/2} & 0.631 & 1.015 \\ \end{array}$	$\begin{array}{cccc} {}^{4}\mathrm{F}_{9/2} & & x10^{3} \\ & & (sec^{-1}) \\ \\ {}^{6}\mathrm{H}_{15/2} & 0.306 & 0.111 & 0.619 \\ {}^{6}\mathrm{H}_{13/2} & 0.691 & 0.844 & 4.6996 \\ {}^{6}\mathrm{H}_{11/2} & 0.031 & 0.045 & 0.2525 \\ \hline \mu s & & & \\ \\ {}^{6}\mathrm{H}_{15/2} & 0.355 & 0.093 & 0.7865 \\ {}^{6}\mathrm{H}_{13/2} & 0.631 & 1.015 & 8.6093 \end{array}$			

- ²⁰ The radiative lifetimes of the ${}^{4}F_{9/2}$ level decreases from 179.5 µs to 105.5 µs with the incorporation of K⁺ ions. From the emission spectra as well as from the values of β_{exp} , it was found that the ${}^{4}F_{9/2} \rightarrow {}^{6}H_{13/2}$ transition sweeps most of the intensity emitted by the phosphor. The radiative transition probability and peak emission 25 cross-section were also found to be higher for ${}^{4}F_{9/2} \rightarrow {}^{6}H_{13/2}$ transition compared to the other transitions. This high $\sigma (\lambda_{p})$ value
- transition compared to the other transitions. This high σ (λ_p) value suggests that the ${}^{4}F_{9/2} \rightarrow {}^{6}H_{13/2}$ transition has potential application for lasing action.

Further, in order to compare the luminescence intensity, the ³⁰ intensity area under the curve of magnetic and electric dipole transitions was determined by fitting with Gaussian distribution function

$$I = I_B + \sum_{i=1}^{n} \frac{A_i}{w_i \sqrt{\pi/2}} e^{2\frac{(\lambda - \lambda_{ci})^2}{w_i^2}}$$
(10)

where *I* is intensity, I_B is the background intensity, w_i is the width ³⁵ at half maximum intensity of the curve, and A_i is area under the curve. λ is wavelength and λ_{ci} is the mean wavelength value corresponding to the transition. All the fittings were carried out in

6 | Journal Name, [year], [vol], oo-oo

the range of 450–510 and 535–615 nm for magnetic and electric dipole transitions, respectively. The relative intensity ratio ${}^{40} \, {}^{4}F_{9/2} \rightarrow {}^{6}H_{13/2}$ to ${}^{4}F_{9/2} \rightarrow {}^{6}H_{15/2}$ transitions can be used as sensitive parameter for understanding the symmetry around the Dy³⁺ in the host material. This parameter is called asymmetric ratio (A_{12}) 30 and is defined as

$$A_{21} = \frac{\int_{510}^{615} I_2 d\lambda}{\int_{450}^{510} I_1 d\lambda}$$
(11)

⁴⁵ where I_1 and I_2 represent the respective integrated intensities of ${}^{4}F_{9/2} \rightarrow {}^{6}H_{15/2}$ and ${}^{4}F_{9/2} \rightarrow {}^{6}H_{13/2}$ transitions of Dy³⁺, respectively. This ratio varies from 2.22 to 2.25 with the variation of Dy³⁺ concentration. When K⁺ is codoped the asymmetric ratio drastically decreases to 1.85. Higher value of A₂₁ indicates more ⁵⁰ asymmetry around Dy³⁺ ligand. This indicates that with K⁺ codoping the symmetry nature of Dy³⁺ ligand increases in the host matrix.

3.2.4. Quantum Yield

External quantum efficiency (EQE) generally known as quantum ⁵⁵ yield (η) is related to number of photons incident on the sample (α) and number of photons emitted (ϵ) as ^{30, 31}

$$\eta = \frac{\varepsilon}{\alpha} = \frac{\int I_{emission}}{\int I_{solvent} - I_{sample}}$$
(12)

where I_{emission} is luminescence emission spectrum of sample, I_{solvent} is the spectrum of light used to excite only solvent and I_{sample} is the ⁶⁰ spectrum of light used for exciting sample. Quantum yields for 2 mol % Dy³⁺ doped and K⁺ codoped phosphors found to be 5% and 8%, respectively.

3.2.5. Decay curve analysis

Theoretically, the measured lifetime (τ_{mes}) of the ${}^{4}F_{9/2}$ fluorescent level can be expressed as 20 :

$$\frac{1}{\tau_{mes}} = \frac{1}{\tau_R} + W_{NR} \tag{13}$$

where τ_{mes} and τ_R are the measured and radiative lifetimes obtained from decay curves and J–O theory respectively. W_{NR} is the nonradiative relaxation rate which includes multi-phonon relaxation 70 (W_{MP}), energy transfer through cross-relaxation (W_{CR}) and several

other non radiative processes. The multi-phonon relaxation is inefficient owing to the significantly large energy gap between the ${}^{4}F_{9/2}$ emitting level and the next-lower level (about 8000 cm⁻¹) as compared with the maximum phonon energy of the matrix lattice 75 27 . So only radiative transition and non-radiative energy transfer relaxation is responsible for the depopulation of the ${}^{4}F_{9/2}$ multiplet. The internal quantum efficiency (IQE) of the excited ${}^{4}F_{9/2}$ state (η) is given by equation

This journal is © The Royal Society of Chemistry [year]

$$\eta = \frac{\tau_{mes}}{\tau_R} \tag{14}$$

This IQE is completely different from the EQE calculated before as explained in ref 32. Figure 8. shows the decay curves of Dy^{3+} ions at 576 nm emission of ${}^{4}F_{9/2}$ excited level CaMoO₄ at 2 mol% s concentration and 2 mol% K⁺ codoped CaMoO₄.

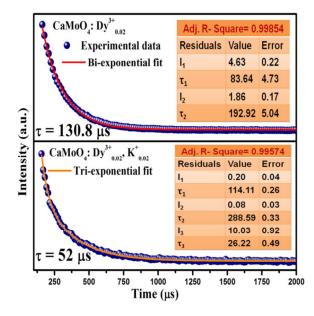

Figure 8. Luminescence decay curve of CaMoO₄ phosphors.

To understand behavior of luminescence decay, the decay data were fitted with different decay equations. It was found that curves ¹⁰ follow two types of exponential decays for Dy^{3+} doped and Dy^{3+}/K^+ codoped phosphors respectively in the host viz, (i) biexponential decay

$$I(t) = I_1 e^{-\frac{1}{\tau_1}} + I_2 e^{-\frac{1}{\tau_2}}$$
(15)

where I_1 and I_2 are intensities at different times and their 15 corresponding lifetimes τ_1 and τ_2 .

The average lifetime in case of a bi-exponential decay can be calculated using the equation

$$\tau_{avg} = \frac{I_1 \tau_1^2 + I_2 \tau_2^2}{I_1 \tau_1 + I_2 \tau_2}$$
(16)

and (ii) triexponential decay

$$_{20} I(t) = I_1 e^{-\frac{1}{\tau_1}} + I_2 e^{-\frac{1}{\tau_2}} + I_3 e^{-\frac{1}{\tau_3}}$$
(17)

where I_1 , I_2 and I_3 are intensities at different times and their corresponding lifetimes τ_1 , τ_2 and τ_3 .

The average lifetime in case of a tri-exponential decay can be calculated using the equation

$$\tau_{avg} = \frac{I_1 \tau_1^2 + I_2 \tau_2^2 + I_3 \tau_3^2}{I_1 \tau_1 + I_2 \tau_2 + I_3 \tau_3}$$
(18)

The multiexponential decay may be explained as ²⁹:

(i) Difference in the nonradiative probability of decays for lanthanide ions at or near the surface and lanthanide ions in the ³⁰ core of the particles.

(ii) Inhomogeneous distribution of the doping ions in the host material leading to the variation in the local concentration.

(iii) The transfer of excitation energy from donor to lanthanide activators.

³⁵ Moreover biexponential decay behavior has been reported for low concentration of lanthanide ions in different matrices which is also the case in the present paper.

The fluorescence lifetime τ_{meas} (τ_{avg}) of the ${}^{4}F_{9/2}$ multiplet was calculated to be 130.80 µs for Dy³⁺ doped CaMoO₄ and decreases to 52 µs for K⁺ codoped CaMoO₄. The deviation between the τ_{meas} and τ_{r} (obtained from J-O theory) may be because the Judd–Ofelt theory is prone to overestimate the value of the radiative lifetime due to its partial inadequacy to predict the the radiative properties ²⁷. Moreover, structural defects and the presence of several Dy³⁺ sites in the matrix may impact the ${}^{4}F_{9/2}$ level emission, leading to τ_{meas} lower than expected. It is clearly seen from the result that after K⁺ codoping, the lifetime reduces. Codoping with K⁺ ion increases the nonradiative decay paths for excited Dy³⁺. This increases the nonrdiative transition probability which increases the radiative so luminescence emission rate ³³. The increase in the total transition probability reduces the lifetime after K⁺ codoping as the lifetime is inverse of the total transition probability.

The IQE for the 2 mol% doped Dy^{3+} and 2 mol% K⁺ compensated CaMoO₄ phosphors were found to be be 72.42% and 49.52% ⁵⁵ respectively.

4. Conclusion

The Judd–Ofelt theory, extended for powder phosphors using excitation spectra instead of conventional absorption spectra, has been successfully applied to evaluate the intensity parameters, radiative transition rates, branching ratios and radiative lifetimes relevant to the ${}^{4}F_{9/2}$ level of Dy³⁺ ion in CaMoO₄ host. A strong yellow and blue emission bands were observed in the visible region upon efficient excitation by near UV light which was well matched with near UV LEDs. The phosphor was characterized by high values of emission cross-section and branching ratio for the ${}^{4}F_{9/2} \rightarrow$ ${}^{6}H_{13/2}$ transition (yellow colour) which increases after K⁺ codoping. As reported previously, the doped/codoped CaMoO₄ phosphors can be utilized in commercial white LEDs and other display devices owing to its colour tunable property. In this present study the

fluorescence and radiative lifetimes of ${}^{4}F_{9/2}$ level with suitable quantum efficiency also indicates that this doped / codoped phosphor may be efficiently used for solid-state yellow lasers pumped by commercially available blue laser diodes.
