This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

*Accepted Manuscripts* are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. This *Accepted Manuscript* will be replaced by the edited, formatted and paginated article as soon as this is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

1 **Fe<sub>2</sub>O<sub>3</sub>-AgBr Nonwoven Cloth with Hierarchical Nanostructures as Efficient**  
2 **and Easily Recyclable Macroscale Photocatalysts <sup>1</sup>**

3 Huihui Zhao,<sup>a</sup> Lisha Zhang,<sup>\*a</sup> Xiaodong Gu,<sup>b</sup> Shijie Li,<sup>a</sup> Bo Li,<sup>b</sup> Huanli Wang,<sup>a</sup> Jianmao  
4 Yang,<sup>c</sup> Jianshe Liu<sup>\*a</sup>

6 **ABSTRACT**

7 A prerequisite for the development of photocatalytic application is to obtain efficient and  
8 easily recycled visible-light-driven (VLD) photocatalysts. Usually, nanosized photocatalysts  
9 exhibit excellent photocatalytic performances but can not be easily recycled, and film-shaped  
10 nanostructured photocatalysts on the substrates (or magnetic photocatalysts) can be easily  
11 recycled but have low surface area and/or high production cost. To solve this problem, herein  
12 we report on the design and preparation of nonwoven cloth based on  
13 semiconductor-semiconductor (Fe<sub>2</sub>O<sub>3</sub>-AgBr as the model) nanojunctions as efficient and  
14 easily recyclable macroscale photocatalysts with nanostructure. Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth  
15 has been prepared by a simple electrospinning-calcination method. Such macroscale cloth is  
16 free-standing and it consists of hierarchical pores with diameters of 600-750 nm and  
17 nanofibers with diameters of 150-350 nm. Furthermore, these nanofibers are constructed from  
18 Fe<sub>2</sub>O<sub>3</sub> and AgBr nanoparticles with diameters of ~ 60 nm. In addition, Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven  
19 cloth has magnetic property and the broadened visible-light photo-response range (400 ~ 750  
20 nm). Under the irradiation of visible light, Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth exhibits higher  
21 photocatalytic activity than Fe<sub>2</sub>O<sub>3</sub> nonwoven cloth and AgBr nonwoven cloth containing the

22 same weight of visible-light-active component, for the degradation of rhodamine B (RhB) and  
23 parachlorophenol (4-CP). Higher photocatalytic activity of Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth  
24 should result from the synergic effects between Fe<sub>2</sub>O<sub>3</sub> and AgBr due to the broadening  
25 photoabsorption and the energy level matching. Importantly, Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth can  
26 be easily transferred and/or recycled by dipping/pulling method and/or external magnetic field,  
27 and it has excellent photocatalytic stability during recycling test. Therefore, this work  
28 provides some insight into the design and development of novel, efficient and easily  
29 recyclable macroscale nonwoven cloths, for future practical photocatalytic application, for  
30 example, degrading organic pollutants in the polluted river.

31

## 32 1. Introduction

33 Over the past years, semiconductor photocatalysis has drawn much attention as a potential  
34 solution to the worldwide energy shortage and environmental purification.<sup>1</sup> A prerequisite for  
35 the development of photocatalysis application is to obtain photocatalysts. To date, TiO<sub>2</sub> is  
36 undoubtedly one of the most excellent and widely used photocatalysts due to its abundance,  
37 chemical stability, low cost, and nontoxicity.<sup>2,3</sup> But a major drawback of TiO<sub>2</sub> is its large  
38 bandgap (~ 3.2 eV) and thus only UV light (typically  $\lambda < 400$  nm; a small fraction of solar  
39 spectrum, ~ 5 %) can be absorbed, which significantly limits the utilization of solar light in  
40 the visible region ( $400 < \lambda < 700$  nm).<sup>2,3</sup> To address this problem, the development of  
41 visible-light-driven (VLD) photocatalysts has attracted increasing attention. Up to now, a  
42 series of single-component semiconductor nanomaterials have been developed as VLD  
43 photocatalysts, such as simple metal oxides (Cu<sub>2</sub>O,<sup>4</sup> W<sub>18</sub>O<sub>49</sub>,<sup>5</sup> Bi<sub>2</sub>O<sub>3</sub>,<sup>6</sup> and etc.), complex  
44 oxides (Bi<sub>2</sub>WO<sub>6</sub>,<sup>7,8</sup> BiOCl,<sup>9</sup> ZnGa<sub>2</sub>O<sub>4</sub>,<sup>10</sup> Ag<sub>3</sub>PO<sub>4</sub>,<sup>11</sup> and etc.), metal sulfides (CdS,<sup>12</sup> ZnIn<sub>2</sub>S<sub>4</sub>,<sup>13</sup>

45 and etc.) and other non-metal materials (g-C<sub>3</sub>N<sub>4</sub><sup>14</sup>). We have also developed some  
46 simple/complex oxides, such as Bi<sub>2</sub>O<sub>3</sub><sup>15</sup> and Bi<sub>2</sub>WO<sub>6</sub> superstructures<sup>7,8</sup> as VLD photocatalysts.  
47 However, there are still some drawbacks hindering their practical application, including the  
48 unsatisfactory visible-light photoresponse range, short photogenerated electron-hole pair  
49 lifetimes, and recycle difficulty. To meet the requirements of future environmental and energy  
50 technologies, it is still necessary to further develop efficient and easily recycled VLD  
51 photocatalysts.

52 On one hand, to improve the photocatalytic activity of VLD photocatalysts, a variety of  
53 strategies have been employed, for example, via suitable textural design, doping, and forming  
54 a semiconductor heterojunction by combining them with metal and/or other semiconductors<sup>16</sup>.  
55 Among these methods, the construction of semiconductor heterojunctions has attracted much  
56 attention due to its simplicity and effectiveness. Recently, we have summarized the design  
57 principles and fabrication methods of semiconductor heterojunction nanomaterials as  
58 efficiently VLD photocatalysts<sup>16</sup>, including the semiconductor-semiconductor heterojunction  
59 (such as WO<sub>3</sub>-BiVO<sub>4</sub><sup>17</sup>, C<sub>3</sub>N<sub>4</sub>-MoS<sub>2</sub><sup>18</sup>, Bi<sub>2</sub>O<sub>3</sub>-Bi<sub>2</sub>WO<sub>6</sub><sup>19</sup> and BiVO<sub>4</sub>-FeOOH-NiOOH<sup>20</sup>), the  
60 semiconductor-metal heterojunction (such as Bi<sub>2</sub>WO<sub>6</sub>-Ag<sup>21</sup>, AgCl-Ag<sup>22</sup> and Ag<sub>3</sub>PO<sub>4</sub>-Ag<sup>23</sup>),  
61 the semiconductor-carbon heterojunction (such as Cu<sub>2</sub>O-carbon nanotubes<sup>24</sup> and  
62 CdS-graphene<sup>25</sup>) and the multicomponent heterojunction (such as, CdS-Au-TiO<sub>2</sub><sup>26</sup>, and  
63 AgBr-Ag-Bi<sub>2</sub>WO<sub>6</sub><sup>27,28</sup>). Compared with single-component semiconductor, these  
64 semiconductor heterojunction nanomaterials exhibit high photocatalytic activity for the  
65 degradation of organic pollutants, hydrogen generation, and/or photocatalytic disinfection.<sup>17-28</sup>  
66 Unfortunately, it is usually difficult to recycle these nanosized photocatalysts in practical  
67 application (such as degrading organic pollutants in lake and/or river), resulting in

68 second-contamination and limiting their large scale application.

69 On the other hand, to effectively recycle catalyst, two strategies have been chiefly  
70 developed. The first kind is to prepare nanostructured semiconductor films on the substrates,  
71 such as nanoparticles-based composite films on ITO glass,<sup>29,30</sup> nanowires/nanotubes-based  
72 film grew on metal foil.<sup>31,32</sup> These film-shaped photocatalysts on the substrate can be easily  
73 recycled, but they suffer from the problems, such as relatively low surface area and/ or high  
74 production cost. The second kind is to prepare nano-photocatalysts with magnetic component,  
75 such as pure Fe<sub>2</sub>O<sub>3</sub>,<sup>33,34</sup> Fe<sub>2</sub>O<sub>3</sub>-Bi<sub>2</sub>WO<sub>6</sub>,<sup>35</sup> Ag-AgI/Fe<sub>3</sub>O<sub>4</sub>@SiO<sub>2</sub> (X= Cl, Br, or I),<sup>36</sup> etc. These  
76 magnetic nanocomposites as photocatalysts can be easily recycled by external magnetic field  
77 in the laboratory, but it is still inconvenient to recycle them in practical application (such as  
78 degrading organic pollutants in lake and/or river). In addition, the photocatalytic  
79 performances of these photocatalysts are still unsatisfied in practical application.

80 Thus, the development of efficient and easily recycled VLD photocatalysts remains a  
81 great challenge. To solve this issue, recently we have deduced that macroscale semiconductor  
82 photocatalysts with nanostructure may have great potential as new generation photocatalysts  
83 that have simultaneously a broad range of visible-light response, superior photocatalytic  
84 activity, high photostability, low cost and easily recycling characteristics, etc.<sup>37</sup> With Ta<sub>3</sub>N<sub>5</sub> as  
85 a model semiconductor, we prepared Ta<sub>3</sub>N<sub>5</sub>-Pt nonwoven cloth with hierarchical nanopores  
86 by an electrospinning-calcination-nitridation-wet impregnation method.<sup>37</sup> Ta<sub>3</sub>N<sub>5</sub>-Pt nonwoven  
87 cloth can be used as an efficient and easily recyclable macroscale photocatalyst with wide  
88 visible-light response. However, this is just a preliminary attempt to develop nonwoven cloth  
89 based on semiconductor-metal heterojunction. A lot of work should be done to further  
90 improve the performance of photocatalyst, for example, by preparing and optimizing

91 nonwoven cloth based on semiconductor-semiconductor and semiconductor-carbon  
92 heterojunction.

93 Among semiconductor photocatalysts,  $\text{Fe}_2\text{O}_3$  nanomaterials with band gap of 2.0 ~ 2.2 eV  
94 have magnetic properties and can utilize a large fraction of visible light, thus they have been  
95 considered to be magnetic and efficient VLD photocatalysts.<sup>33,34</sup> In addition, AgBr with band  
96 gap of 2.6 eV has also been proved to be an excellent VLD photocatalyst.<sup>38,39</sup> Herein, by  
97 using  $\text{Fe}_2\text{O}_3$  and AgBr as the models of semiconductors, we report the design and preparation  
98 of nonwoven cloth based on semiconductor-semiconductor ( $\text{Fe}_2\text{O}_3$ -AgBr) nanojunctions.  
99 Macroscale  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth consists of plenty of nanofibers, and these  
100 nanofibers are in fact constructed from  $\text{Fe}_2\text{O}_3$  and AgBr nanoparticles. The  $\text{Fe}_2\text{O}_3$ -AgBr  
101 nonwoven cloth can be used as an efficient macroscale semiconductor heterojunction  
102 photocatalyst with nanostructure, for the degradation of both rhodamine B (RhB) dye and  
103 parachlorophenol (4-CP) under visible-light irradiation. Importantly,  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven  
104 cloth can be easily recycled with good stability, by dipping/pulling method and/or external  
105 magnetic field.

106

## 107 **2. Experimental**

### 108 **2.1. Materials**

109 Ferric acetylacetonate ( $\text{Fe}(\text{acac})_3$ ), polyvinyl pyrrolidone (PVP,  $M_w \approx 1300000$ ),  
110 cetyltrimethylammonium bromide (CTAB), silver nitrate, ammonium hydroxide (25 wt%  
111  $\text{NH}_3$ ), ethanol (> 99.7 %) and acetic acid were purchased from Sinopharm Chemical Reagent  
112 Co., Ltd. They were all analytical grade and used as received without further purification.

### 113 **2.2. Preparation of catalysts**

114  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth was synthesized by an electrospinning-calcination method.  
115 In a typical process,  $\text{Fe}(\text{acac})_3$  (0.65 g, 1.84 mmol), PVP (1.5 g) and CTAB (0.35 g, 0.96  
116 mmol) were dissolved in ethanol (16 mL). Then the ethanol solution was magnetically stirred  
117 for 30 min, forming a turbid solution. Subsequently, ammonia water (1 mL) containing  
118  $\text{AgNO}_3$  (0.10 g, 0.59 mmol) was quickly added to the above solution. After vigorously  
119 stirring for 24 h, the precursor solution was loaded into a plastic syringe, and the feeding rate  
120 was kept constant at  $0.5 \text{ mL h}^{-1}$  using a syringe pump. A high voltage of 16 kV was applied  
121 between the orifice and grounded aluminum foil at a distance of 15 cm. The collected  
122 composite cloth was taken out carefully, hydrolyzed in air for 12 h, and calcined at  $550^\circ\text{C}$  in  
123 air for 6 h to obtain  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth.

124 For comparison,  $\text{Fe}_2\text{O}_3$  nonwoven cloth as well as AgBr nonwoven cloth was also  
125 synthesized by an electrospinning-calcination method. The precursor solution for  $\text{Fe}_2\text{O}_3$   
126 nonwoven cloth was the ethanol solution (16 mL) containing 2.08 g  $\text{Fe}(\text{acac})_3$ , 1.12 g PVP  
127 and 4.8 mL acetic acid. Then the electrospinning process was performed under the same  
128 conditions with the preparation of  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth. The precursor solution for  
129 AgBr nonwoven cloth was the ethanol solution (16 mL) containing 0.35 g CTAB, 1.5 g PVP,  
130 0.10 g  $\text{AgNO}_3$  and 1 mL ammonia water; and the electrospinning-calcination process was the  
131 same with those of  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth.

### 132 **2.3. Photocatalysts characterization**

133 The sizes and morphologies of samples were examined by field emission scanning  
134 electron microscope (FE-SEM, Hitachi S-4800) and high-resolution transmission electron  
135 microscope (HR-TEM, JEOL JEM-2010F). X-Ray diffraction (XRD) was measured with a  
136 D/max-2550 PC X-ray diffractometers using  $\text{Cu-K}\alpha$  radiation ( $\lambda = 0.15418 \text{ nm}$ ).

137 Energy-dispersive X-ray spectroscopy (EDS) of the sample was carried out on a Bruker  
138 Quantax 400 EDS system during SEM characterization. The optical diffuse reflectance  
139 spectra of the samples were measured on a UV-VIS-NIR scanning spectrophotometer  
140 (UV-3101PC, Shimadzu) using an integrating sphere accessory. Magnetic properties were  
141 measured with a physical property measurement system (PPMS-9T (EC-II)).

#### 142 **2.4. Photocatalytic test and reusability of nonwoven cloth**

143 Photocatalytic activities of the photocatalysts were tested by degrading rhodamine B (RhB)  
144 and parachlorophenol (4-CP), using a 300 W xenon lamp (Beijing Perfect Light Co. Ltd.,  
145 Beijing) as light source. Light was passed through a UV cut-off filter ( $\lambda > 400$  nm), and then  
146 was focused onto a 100-mL beaker containing aqueous solution of RhB (40 mL,  $4.79 \text{ mg L}^{-1}$ ,  
147  $\text{pH} = 7.0$ ) or 4-CP (50 mL,  $10 \text{ mg L}^{-1}$ ). The temperature of the reaction solution was  
148 controlled at  $20 \pm 2^\circ\text{C}$  by circulation cooling installation. In each experiment, a feasible  
149 amount of photocatalysts were added into aqueous solution. Prior to irradiation, the  
150 suspensions were magnetically stirred for 60 min in the dark to achieve adsorption-desorption  
151 equilibrium between the photocatalyst and the target organic pollutant.

152 When the remaining RhB concentration needed to be measured, at 10 min irradiation time  
153 intervals, 1.5 mL aliquot was collected, centrifuged, and then filtered through a Millipore  
154 filter (pore size  $0.22 \mu\text{m}$ ) to remove the catalysts for analysis. The filtrate was analyzed by  
155 recording variations at the wavelength of maximal absorption (553 nm) in the UV-vis spectra  
156 of RhB with a U-2910 (Hitachi, Japan) spectrophotometer. Meanwhile, to study the pH effect  
157 on the photocatalytic activity, the initial pH of RhB aqueous solution was tuned to be 3, 5, 7,  
158 9, or 11 by adding  $\text{H}_2\text{SO}_4$  ( $0.1 \text{ mol L}^{-1}$ ) or  $\text{NaOH}$  ( $0.1 \text{ mol L}^{-1}$ ) aqueous solution, and the  
159 degradation efficiency of RhB by  $\text{Fe}_2\text{O}_3\text{-AgBr}$  nanowoven cloth was measured.

160 When the remaining 4-CP concentration needed to be measured, at 20 min irradiation time  
161 intervals, 5 mL aliquot was collected, centrifuged, and then filtered to be analyzed. The 4-CP  
162 concentrations in the solutions were analyzed by high-performance liquid chromatography  
163 (HPLC) using an Agilent 1100 series (USA) equipped with a diode array detector (DAD).  
164 The mobile phase consisted of 80 % acetonitrile and 20 % water at a flow rate of 0.5 mL  
165 min<sup>-1</sup>. The maximum absorption wavelength was detected at 280 nm.

166 To test the mineralization degree of 4-CP, the photodegradation by Fe<sub>2</sub>O<sub>3</sub>-AgBr  
167 nanowoven cloth was performed under visible-light irradiation. 300 mg Fe<sub>2</sub>O<sub>3</sub>-AgBr  
168 nonwoven cloth was immersed to 100 mL 4-CP solution (20 mg L<sup>-1</sup>). During the  
169 photocatalytic process, at 30 min irradiation time intervals, 10 mL aliquot was collected,  
170 centrifuged, and then filtered through a Millipore filter (pore size 0.22 μm) to remove the  
171 catalyst particulates for analysis. The total organic carbon (TOC) value of 4-CP was detected  
172 by a Shimadzu TOC-V<sub>CPH</sub> total organic carbon analyzer.

173 To test the stability and reusability of Fe<sub>2</sub>O<sub>3</sub>-AgBr nanowoven cloth, four consecutive  
174 cycles of photodegrade RhB were proceed under visible-light irradiation. After one cycle  
175 photocatalytic reaction, the photocatalysts were recycled by dipping/pulling method (2 times)  
176 or external magnetic field (1 time). Then, the collected photocatalysts were washed  
177 thoroughly with water and dried at 75 °C for 12 h. Next, the dried Fe<sub>2</sub>O<sub>3</sub>-AgBr nanowoven  
178 cloth was immersed to photodegrade fresh RhB aqueous solution (40 mL, 4.79 mg L<sup>-1</sup>) again.

179

### 180 **3. Results and discussion**

#### 181 **3.1. Preparation and characterization of the nonwoven cloth**

182 Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth was prepared by an electrospinning-calcination method, as

183 demonstrated in Fig. 1. First step was to prepare PVP/Fe<sub>2</sub>O<sub>3</sub>-AgBr/CTAB composite  
184 nonwoven cloth, by electrospinning the ethanol solution (16 mL) containing 0.65 g Fe(acac)<sub>3</sub>,  
185 0.35 g CTAB, 1.5 g PVP, 0.10 g AgNO<sub>3</sub> and 1 mL ammonia water at a high voltage of 16 kV,  
186 and followed by the hydrolysis process. The as-prepared PVP/Fe<sub>2</sub>O<sub>3</sub>-AgBr/CTAB composite  
187 nonwoven cloth is yellow, and its typical photograph (area:  $\sim 6 \times 4 \text{ cm}^2$ ) is shown in Fig. 2a.  
188 In fact, in the electrospinning process, the area of the nonwoven cloth can be easily tuned in a  
189 broad range ( $10^{-4} \sim 1 \text{ m}^2$ ) by changing the collecting region of aluminum foil. This macroscale  
190 nonwoven cloth is composed of plenty of individual straight fibers with smooth surface and  
191 diameters ranging from 350 to 400 nm, as revealed in SEM images (Fig. 2b and 2c). In  
192 addition, among fibers in the nonwoven cloth, there are many hierarchical pores with  
193 diameter of 600-750 nm (Fig. 2b and 2c).

194 The second step was to calcine the composite nonwoven cloth at 550 °C in air for 6 h, for  
195 removing organic component and obtaining inorganic Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth. It should  
196 be noted that the area of Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth was reduced to  $\sim 1 \times 1.5 \text{ cm}^2$ , since  
197 nonwoven cloth with larger area may be more fragmented. After the calcination process, the  
198 color of the nonwoven cloth turned from yellow to red-brown, as demonstrated vividly in Fig.  
199 2d. This Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth has the macroscopic morphology and is still  
200 freestanding (Fig. 2d), indicating that the calcination process has no obvious adverse effect on  
201 the macroscopic morphology. SEM images (Fig. 2e and 2f) reveal that Fe<sub>2</sub>O<sub>3</sub>-AgBr cloth is  
202 also composed of hierarchical pores (diameter: 600-750 nm) and fibers. The diameters of  
203 Fe<sub>2</sub>O<sub>3</sub>-AgBr fibers shrink to 150-350 nm, and these fibers also interweave and/or stick  
204 together, which results from the decomposition of PVP/CTAB component and high  
205 temperature anneal of Fe<sub>2</sub>O<sub>3</sub>-AgBr component. Further information about Fe<sub>2</sub>O<sub>3</sub>-AgBr

206 nanofiber is obtained from the TEM image (Fig. 2g), and it confirms that the  $\text{Fe}_2\text{O}_3\text{-AgBr}$   
207 nanofiber with diameter of about 200 nm is comprised of plenty of nanoparticles with  
208 diameters of  $\sim 60$  nm, probably resulting in high surface area. The high-resolution TEM  
209 image (Fig. 2h) taken from one nanoparticle in the fiber (Fig. 2g) demonstrates that the lattice  
210 spacings are 0.271 and 0.333 nm, which are in good agreement with the values for the  $\text{Fe}_2\text{O}_3$   
211 (104) plane (JCPDS Card. 87-1166) and for the AgBr (111) plane (JCPDS Card. 79-0149),  
212 respectively. Thus, one can confirm the formation of  $\text{Fe}_2\text{O}_3\text{-AgBr}$  nonwoven cloth with  
213 well-defined nanojunctions.

214 Subsequently, the phase and composition of  $\text{Fe}_2\text{O}_3\text{-AgBr}$  nonwoven cloth were further  
215 investigated. Fig. 3a shows the XRD pattern of  $\text{Fe}_2\text{O}_3\text{-AgBr}$  nonwoven cloth as well as the  
216 standard XRD patterns of AgBr (JCPDS Card. 79-0149) and  $\text{Fe}_2\text{O}_3$  (JCPDS Card. 87-1166).  
217 Obviously, XRD pattern of  $\text{Fe}_2\text{O}_3\text{-AgBr}$  nonwoven cloth can be indexed as the mixture of  
218  $\text{Fe}_2\text{O}_3$  crystalline and AgBr crystalline. Some diffraction peaks at  $30.94^\circ$ ,  $44.33^\circ$  and  $55.04^\circ$   
219 are assigned to (200), (220) and (222) crystal planes of cubic phase AgBr (JCPDS Card.  
220 79-0149), respectively. In addition, some diffraction peaks at  $24.15^\circ$ ,  $33.3^\circ$ ,  $35.8^\circ$ ,  $41.0^\circ$ ,  
221  $49.6^\circ$ ,  $54.8^\circ$ ,  $62.6^\circ$ ,  $64.2^\circ$  are corresponding to (012), (104), (110), (113), (024), (116), (214)  
222 and (300) crystal planes of rhombohedral  $\text{Fe}_2\text{O}_3$  (JCPDS Card. 87-1166), respectively. These  
223 results confirm that there are both  $\text{Fe}_2\text{O}_3$  and AgBr species in the  
224 semiconductor-semiconductor nanojunction system, which is in good agreement with the  
225 HR-TEM analysis (Fig. 2h). In addition, since  $\text{Fe}_2\text{O}_3\text{-AgBr}$  nonwoven cloth was prepared by  
226 electrospinning-calcination process without washing/centrifugation step,  $\text{Fe}(\text{acac})_3$  (1.84  
227 mmol) and  $\text{AgNO}_3$  (0.59 mmol) should be converted completely to  $\text{Fe}_2\text{O}_3$  and AgBr species  
228 without Fe/Ag element loss. The resulting  $\text{Fe}_2\text{O}_3\text{-AgBr}$  nonwoven cloth was about 0.26 g, and

229 it should consist of 0.92 mmol ( $\sim 0.147$  g, 57 wt %)  $\text{Fe}_2\text{O}_3$  and 0.59 mmol ( $\sim 0.111$  g, 43  
230 wt %) AgBr with Fe/Ag molar ratio of about 3.1. EDS pattern (Fig. 3b) further reveals that  
231 there are O, Fe, Br and Ag elements in the  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth, and the molar ratio  
232 of Fe to Ag is equal to 2.9 which is close to the precursor Fe/Ag molar ratio (3.1). Therefore,  
233 one can deduce that  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth was composed of  $\text{Fe}_2\text{O}_3$  (57 wt %) and  
234 AgBr (43 wt %) crystallines.

235 The magnetic property of  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth was measured at 300 K with the  
236 magnetic field swept back and forth between 30 and -30 kOe. Fig. 4a shows a nonlinear and  
237 reversible behavior with a magnetic hysteresis loop. And a detailed partial image is shown in  
238 the inset of Fig. 4a. The relevant saturation magnetization ( $M_s$ ), remanent magnetization ( $M_r$ )  
239 and coercivity ( $H_c$ ) of  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth were 8.42 emu/g, 1.2 emu/g and 160 G  
240 respectively, revealing super paramagnetic behavior. Magnetic characteristic provides a  
241 promising way for catalyst recycling because it not only prevents the loss of catalyst but also  
242 saves time. In our case, the  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth could be precipitated in the water  
243 (Fig. 4b), but it could be magnetically pulled to the side of the bottle when an external column  
244 magnet was applied on the same side of the bottle (Fig. 4c). These facts reveal that  
245  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth can be efficiently recycled by external magnetic field.

246 The optical absorption of  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth was measured by an UV-vis  
247 spectrometer (Fig. 5). For comparison, the optical absorption of  $\text{Fe}_2\text{O}_3$  nonwoven cloth  
248 prepared by electrospinning-calcination was also tested.  $\text{Fe}_2\text{O}_3$  nonwoven cloth exhibits  
249 photoabsorption from the UV to visible light with edge at approximately 610 nm, which  
250 agrees well with the reported value for the band gap ( $E_g = 2.0$  eV) of bulk  $\text{Fe}_2\text{O}_3$ .<sup>33</sup> The weak  
251 absorption from 610 nm to 750 nm is occurred, which should result from the effective light

252 scattering. Importantly,  $\text{Fe}_2\text{O}_3\text{-AgBr}$  nonwoven cloth displays a broader-spectrum  
253 photoabsorption from the UV light to visible light region with edge at approximately 630 nm  
254 and the weak absorption from 630 nm to 750 nm, indicating a substantial red shift of  
255 photoabsorption. Furthermore, the photoabsorption of  $\text{Fe}_2\text{O}_3\text{-AgBr}$  nonwoven cloth in the  
256 whole visible light region (400 nm ~ 750 nm) is higher than that of  $\text{Fe}_2\text{O}_3$  nonwoven cloth.  
257 These facts demonstrate that the region of visible-light photo-response of  $\text{Fe}_2\text{O}_3\text{-AgBr}$   
258 nonwoven cloth can be broadened and enhanced due to the construction of the heterojunction.  
259 Therefore, VLD photocatalytic activity of  $\text{Fe}_2\text{O}_3\text{-AgBr}$  nonwoven cloth can be expected to be  
260 more excellent compared with that of pure  $\text{Fe}_2\text{O}_3$  nonwoven cloth.

### 261 **3.2 Photocatalytic performances of $\text{Fe}_2\text{O}_3\text{-AgBr}$ nonwoven cloth**

262 In order to investigate the potential of  $\text{Fe}_2\text{O}_3\text{-AgBr}$  nonwoven cloth as VLD  
263 photocatalyst, the photocatalytic activity of macroscopic  $\text{Fe}_2\text{O}_3\text{-AgBr}$  cloth was evaluated by  
264 immersing the cloth in the solution containing RhB dye or 4-CP as the model pollutant (Fig.  
265 6a). For comparison,  $\text{Fe}_2\text{O}_3$  and AgBr nonwoven cloths were also prepared and used as the  
266 photocatalysts.

267 When RhB dye was used as the model of colored organic pollutant, the photocatalytic  
268 degradation efficiency by macroscopic  $\text{Fe}_2\text{O}_3\text{-AgBr}$  nonwoven cloth (20 mg, containing 11.4  
269 mg  $\text{Fe}_2\text{O}_3$  and 8.6 mg AgBr) was evaluated under visible light irradiation ( $\lambda > 400$  nm) (Fig.  
270 7a). For comparison, the degradation efficiencies of RhB dye without photocatalysts (blank  
271 test) and by different photocatalysts with the same weight of each component (11.4 mg pure  
272  $\text{Fe}_2\text{O}_3$  nonwoven cloth, or 8.6 mg pure AgBr nonwoven cloth) were determined with  
273 otherwise identical conditions, respectively, as shown in Fig. 7a. The blank test indicates that  
274 the degradation of RhB is extremely slow without photocatalysts under visible light

275 illumination (Fig. 7a-A). When the pure  $\text{Fe}_2\text{O}_3$  nonwoven cloth (11.4 mg) was used as the  
276 photocatalyst, the degradation of RhB was also slow, and only 13.7 % RhB could be removed  
277 after 60 min of reaction (Fig. 7a-B). By using the pure AgBr nonwoven cloth (8.6 mg) as the  
278 photocatalyst, 25.9 % of RhB was photocatalytically degraded after 60 min, indicating low  
279 photocatalytic activity (Fig. 7a-C). Importantly, when  $\text{Fe}_2\text{O}_3$ -AgBr cloth was used as the  
280 photocatalyst, 91.8 % of RhB could be degraded after 60 min, indicating the highest  
281 photocatalytic activity, as shown in Fig. 7a-D.

282 Subsequently, the effect of pH value of solutions on photodegradation efficiency of RhB  
283 was studied by using  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth (20 mg) as the photocatalyst, and the  
284 degradation efficiency at 60 min was determined (Fig. 7b). Obviously, when the pH was acid  
285 or alkaline, the photodegradation efficiency was relatively slow (66.5 % at pH = 3 or 70.7 %  
286 at pH = 11). However, the photodegradation efficiency of RhB enhanced when the RhB  
287 aqueous solution was close to neutral condition (75.3 % at pH = 5 or 76.0 % at pH = 9).  
288 Especially, when the pH value was 7.0, 91.8 % RhB could be photodegraded after 60 min.  
289 Previous studies reveal that the photodegradation of dye pollutants is pH-dependent, chiefly  
290 resulting from the variation of surface charge of catalysts and the structure of the dye  
291 molecule with pH.<sup>27</sup> We also believe that the variation of degradation efficiency of RhB  
292 should be attributed to surface charge of catalysts and the structure of the dye molecule.

293 When 4-CP was used as the model of colorless organic pollutant, the photocatalytic  
294 degradation efficiencies were evaluated by blank test (without photocatalysts) or immersing  
295 pure  $\text{Fe}_2\text{O}_3$  nonwoven cloth (28.5 mg), pure AgBr nonwoven cloth (21.5 mg), or  $\text{Fe}_2\text{O}_3$ -AgBr  
296 nonwoven cloth (50 mg, containing 28.5 mg  $\text{Fe}_2\text{O}_3$  and 21.5 mg AgBr) in 4-CP aqueous  
297 solution under visible light irradiation ( $\lambda > 400$  nm) (Fig. 8a). 4-CP as a typical pollutant has

298 no photolysis and no visible light absorption characteristics in the photodegradation process.  
299 The blank test reveals that there was no photodegradation of 4-CP after 120 min of visible  
300 irradiation (Fig. 8a-A). Similarly, when pure  $\text{Fe}_2\text{O}_3$  nonwoven cloth was used as the  
301 photocatalyst, the photodegradation of 4-CP was also very slow and only 5.5 % 4-CP was  
302 degraded after 120 min (Fig. 8a-B). In addition, with AgBr nonwoven cloth as the  
303 photocatalyst, the photodegradation efficiency of 4-CP increased to 52.8 % after 120 min (Fig.  
304 8a-C). Importantly,  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth could degrade 74.2 % 4-CP after 120 min  
305 (Fig. 8a-D), also indicating the highest photocatalytic activity of  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth  
306 among these nonwoven cloths.

307 It is well known that mineralization is the ultimate goal in pollutant treatment, and total  
308 organic carbon (TOC) value is usually used as an important index for the mineralization  
309 degree of organic species. Herein, the mineralization of 4-CP was investigated by immersing  
310 300 mg  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth in 4-CP (100 mL, 20 mg  $\text{L}^{-1}$ ) solution under visible light  
311 irradiation ( $\lambda > 400$  nm), and TOC value was recorded during the photocatalytic process (Fig.  
312 8b). Obviously, with the increase of irradiation time, the TOC concentration continuously  
313 decreased, indicating that 4-CP was steadily mineralized. After four hours, the TOC  
314 concentration decreases from 12.23 mg  $\text{L}^{-1}$  to 3.58 mg  $\text{L}^{-1}$ , reaching a high mineralization  
315 ratio of 70.7 %. This fact demonstrates that  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth can efficiently  
316 degrade and mineralize organic pollutants under visible light irradiation.

317 To further confirm the role of the nanojunction in  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth, the  
318 degradation efficiencies of RhB and 4-CP were compared (Fig. 9). According to Fig. 7a and  
319 8a, pure  $\text{Fe}_2\text{O}_3$  nonwoven cloth could degrade 13.7 % RhB after 60 min or 5.5 % 4-CP after  
320 120 min, while pure AgBr nonwoven cloth could degrade 25.9 % RhB after 60 min or 52.8 %

321 4-CP after 120 min. Thus, the total degradation efficiencies by two individual photocatalysts  
322 ( $\text{Fe}_2\text{O}_3$  nonwoven cloth and AgBr nonwoven cloth) were 39.6 % (13.7 % + 25.9 %) for RhB  
323 after 60 min, or 58.3 % (5.5 % + 52.8 %) for 4-CP after 120 min. More importantly,  
324  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth could degrade 91.8 % RhB after 60 min or 74.2 % 4-CP after  
325 120 min, which were both higher than the total degradation efficiencies (39.6 % and 58.3 %)  
326 by pure  $\text{Fe}_2\text{O}_3$  nonwoven cloth and pure AgBr nonwoven cloth for RhB and 4-CP degradation.  
327 These results strongly reveal that there is a synergic effect in  $\text{Fe}_2\text{O}_3$ -AgBr heterojunction  
328 nonwoven cloth, which is similar to the phenomenon in our previous study.<sup>27</sup>

329 Based on the above results, one can conclude that  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth exhibits  
330 higher photocatalytic activity than pure  $\text{Fe}_2\text{O}_3$  nonwoven cloth and pure AgBr nonwoven  
331 cloth with the same weight of each component, even higher than the sum of photocatalytic  
332 efficiencies by pure  $\text{Fe}_2\text{O}_3$  nonwoven cloth and pure AgBr nonwoven cloth, for the  
333 photodegradation of RhB and 4-CP. The possible reasons for the highest photocatalytic  
334 activity of  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth are analyzed, and we believe that there are chiefly  
335 two reasons. One reason is the substantial broadening of the photoabsorption range from the  
336 UV to visible-light range, as shown in Fig. 5. Undoubtedly, this broadening facilitates the  
337 absorption of more visible light, which produces more photogenerated holes and electrons  
338 consequently. The other reason should be due to the energy level matching between  $\text{Fe}_2\text{O}_3$  and  
339 AgBr, as shown in the energy band diagram (Fig. 6b).<sup>38,40</sup> Under the irradiation of visible  
340 light, both  $\text{Fe}_2\text{O}_3$  semiconductor and AgBr semiconductor can generate electrons in the  
341 conduction band (CB) and holes in the valence band (VB). As summarized in our recent  
342 review,<sup>16</sup> since the CB level of  $\text{Fe}_2\text{O}_3$  semiconductor is lower than that of AgBr  
343 semiconductor, electrons in the CB of AgBr semiconductor can be transferred to that of  $\text{Fe}_2\text{O}_3$

344 semiconductor (Fig. 6b). Furthermore, the VB level of  $\text{Fe}_2\text{O}_3$  semiconductor is lower than that  
345 of AgBr semiconductor, holes in the VB of  $\text{Fe}_2\text{O}_3$  semiconductor can be transferred to that of  
346 AgBr semiconductor (Fig. 6b). As a result, less of a barrier exists due to the promoted  
347 separation and migration of photogenerated carriers by the internal field. So the probability of  
348 electron-hole recombination can be decreased. Larger numbers of electrons stored on the  
349  $\text{Fe}_2\text{O}_3$  surface and holes stored on the AgBr surface can, respectively, participate in  
350 photoredox reactions to degrade organic pollution directly or indirectly, which can enhance  
351 the photocatalytic reaction greatly, just as presented in Fig. 7a and 8a.

352 Most importantly, the macroscale  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth can be easily transferred  
353 and/or recycled in photocatalytic application. To evaluate the stability and reusability of  
354 macroscale  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth, a recycling test was performed, as shown in Fig. 10.  
355 The photodegradation of RhB was monitored for four cycles (each cycle lasted 60 min). After  
356 each cycle, the macroscale  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth was recycled by dipping/pulling  
357 method and/or external magnetic field, then washed with water. Afterward, the cloth was  
358 immersed in the same volume (40 mL) of fresh RhB solution with the same concentration  
359 ( $4.79 \text{ mg L}^{-1}$ ) again. For the first cycle, 91.8 % RhB was degraded after 60 min reaction time.  
360 Subsequently, the degradation efficiency of RhB was 88.6 %, 85.2 % and 79.8 % for the  
361 second, third and fourth cycle, respectively (Fig. 10). This fact indicates a slight decrease of  
362 degradation efficiency, and the reason for the decrease was further investigated. After 4 times  
363 photocatalytic tests,  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth was recycled, and its XRD pattern was also  
364 analyzed (Fig. 3a, blue line). Obviously, there is no change of the crystalline phases compared  
365 with the as-prepared  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven cloth, which indicates that  $\text{Fe}_2\text{O}_3$ -AgBr  
366 nonwoven cloth has excellent stability. In addition, we also found that  $\text{Fe}_2\text{O}_3$ -AgBr nonwoven

367 cloth has good stability in the solution with a wide pH range (3-11). For example, when the  
368 cloth was immersed in acidic solution (pH= 4.5) for 60 min, the mass loss of Fe<sub>2</sub>O<sub>3</sub>-AgBr  
369 nonwoven cloth was only 4.13 wt%. However, during photocatalytic process, we found that  
370 Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth was relatively fragmented, and there was a mass loss from 20  
371 mg for the first cycle to 16.8 mg for the fourth cycle. Thus, the slight decrease of degradation  
372 efficiency should be attributed to the mass loss instead of the performance change of  
373 Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth. Further work should be carried out to prepare efficient and  
374 flexible macroscale Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth with larger area and better mechanical  
375 properties.

376

#### 377 **4. Conclusions**

378 In summary, Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth has been synthesized by a  
379 electrospinning-calcination method. Such macroscale cloth consists of nanofibers that were in  
380 fact constructed from Fe<sub>2</sub>O<sub>3</sub> and AgBr nanoparticles. Under visible light illumination,  
381 Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth exhibits excellent photocatalytic activity for the degradation of  
382 RhB and 4-CP, compared with nonwoven cloths based on single visible-light response  
383 component (pure Fe<sub>2</sub>O<sub>3</sub> nonwoven cloth and pure AgBr nonwoven cloth). Furthermore,  
384 Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth can be easily transferred and/or recycled with good stability, by  
385 dipping/pulling method and/or external magnetic field. Therefore, Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth  
386 has great potential as efficient and easily recyclable VLD photocatalysts for future practical  
387 photocatalytic application, for example, degrading organic pollutants in the polluted  
388 river/lake.

481 **Figure Captions:**

482 **Fig. 1.** Schematic illustration of the preparation of Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth.

483 **Fig. 2.** The photos and microscopy images of nonwoven cloth: (a-c) as-prepared  
484 PVP/Fe<sub>2</sub>O<sub>3</sub>-AgBr/CTAB composite nonwoven cloth, (d-f) Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth, (g-h)  
485 TEM images of one nanofiber from Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth.

486 **Fig. 3.** (a) XRD patterns of the as-prepared Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth, the used  
487 Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth after photocatalytic test, and the standard patterns of AgBr  
488 (JCPDS Card. 79-0149) and Fe<sub>2</sub>O<sub>3</sub> (JCPDS Card. 87-1166), and (b) EDS pattern of  
489 Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth.

490 **Fig. 4.** (a) Magnetic hysteresis loops of Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth, a detailed partial image  
491 is shown in the inset of the figure, and magnetic separation test of Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven  
492 cloth: (b) without the external magnet field, and (c) with the external magnet field.

493 **Fig. 5.** The ultraviolet-visible diffuse reflectance spectra of Fe<sub>2</sub>O<sub>3</sub> cloth and Fe<sub>2</sub>O<sub>3</sub>-AgBr  
494 cloth.

495 **Fig. 6.** (a) Schematic illustration of experimental setups and photocatalytic process, and (b)  
496 energy band diagram of the Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth.

497 **Fig. 7.** (a) The degradation efficiency of RhB (4.79 mg L<sup>-1</sup>, 40 mL) by blank test (without  
498 photocatalyst), pure Fe<sub>2</sub>O<sub>3</sub> nonwoven cloth (11.4 mg), pure AgBr nonwoven cloth (8.6 mg),  
499 or Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth (20 mg, containing 11.4 mg Fe<sub>2</sub>O<sub>3</sub> and 8.6 mg AgBr), and (b)  
500 the effect of pH on the photodegradation efficiency of RhB (4.79 mg L<sup>-1</sup>, 40 mL) by  
501 Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth (20 mg) after 60 min reaction.

502 **Fig. 8.** (a) The degradation efficiency of 4-CP (10 mg L<sup>-1</sup>, 50 mL) by blank test (without

503 photocatalysts), pure Fe<sub>2</sub>O<sub>3</sub> nonwoven cloth (28.5 mg), pure AgBr nonwoven cloth (21.5 mg),  
504 or Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth (50 mg, containing 28.5 mg Fe<sub>2</sub>O<sub>3</sub> and 21.5 mg AgBr), and (b)  
505 the TOC removal efficiency during the 4-CP (20 mg L<sup>-1</sup>, 100 mL) photodegradation process  
506 by Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth (300 mg).

507 **Fig. 9.** The comparison of degradation efficiencies of RhB after 60 min and 4-CP after 120  
508 min, by Fe<sub>2</sub>O<sub>3</sub> nonwoven cloth, AgBr nonwoven cloth and Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth.

509 **Fig. 10.** Cycling photocatalytic test of Fe<sub>2</sub>O<sub>3</sub>-AgBr nonwoven cloth (20 mg).
