32 **Abstract**

33

34

35 Rate coefficients for the reactions of ozone with the biogenic aldehydes *trans*-2-heptenal,
36 *trans*-2-octenal and *trans*-2-nonenal have been determined at 298 K and (990 ± 10) mbar of
37 pressure in air in an environmental chamber using in situ FTIR spectroscopy to monitor the
38 reactants. The following rate coefficients in units of $k_{O_3} \times 10^{18}$ ($\text{cm}^3/\text{molecule}^{-1} \text{ s}^{-1}$) were
39 obtained: (2.47 ± 0.73) for *trans*-2-heptenal, (2.37 ± 0.68) for *trans*-2-octenal and $(2.05 \pm$
40 $0.20)$ for *trans*-2-nonenal.

41 It is shown that rate coefficients for the addition of O_3 molecules and OH radicals to the
42 double bond of alkenes and unsaturated and oxygenated volatile organic compounds
43 (OVOCs) at 298 K are related to a good approximation by the expression: $\log k_{OH} = 0.16$
44 $\log k_{O_3} - 7.55$. Furthermore, a correlation between the reactivity of unsaturated VOCs
45 toward O_3 molecules and the energies of the Highest Occupied Molecular Orbit (HOMO)
46 of the unsaturated VOCs is presented and potential atmospheric implications of the results
47 are discussed.

56

57 Introduction

58

59 Volatile Organic Compounds (VOCs) emitted from vegetation, often referred to as biogenic
60 volatile organic compounds (BVOCs), are considered to be the main source of reactive
61 species in the troposphere^{1,2,3}. Aldehydes play an important role in atmospheric chemistry
62 since they are recognized as important key precursors in the formation of tropospheric
63 ozone and OH radicals.⁴⁻⁷ They are also potential prolific sources of secondary organic
64 aerosols through their reactions with atmospheric oxidants and photolysis.⁸

65 Aldehydes are ubiquitous gaseous chemical constituents in the atmosphere and are emitted
66 by a variety of sources. They arise, for example, from incomplete fossil fuel combustion,
67 are emitted by vegetation and are produced during biomass burning. The photochemical
68 oxidation of most VOCs in the atmosphere results in the formations of aldehydes to some
69 degree.⁴⁻⁷

70 As mentioned above, in the troposphere aldehydes can be photolyzed^{6,7,9} and will also be
71 subject to reaction with the main atmospheric oxidants OH radicals, NO₃ radicals and O₃
72 molecules. In the marine boundary layer and coastal regions reactions with Cl atoms can
73 also be important. The combination of the photodissociation of aldehydes and reaction with
74 the atmospheric oxidants represents, in many cases, an important source of free radicals in
75 the lower atmosphere which can significantly influence the atmospheric oxidation
76 capacity.^{7,10}

77 A number of reviews on the gas-phase kinetics of the reactions of OH, NO₃, O₃ and Cl with
78 different unsaturated aldehydes are available in the literature.⁴⁻⁷ For long chain (>C₄)
79 unsaturated aldehydes rate coefficients have been reported, by different groups using

80 absolute and relative kinetic techniques, for the reaction of OH with *E*-2-pentenal, *E*-2-
81 hexenal, *E*-2-heptenal, *E*-2-octenal and *E*-2-nonenal at room temperature and in some cases
82 also as a function of temperature.^{6,7} In the case of NO₃, rate coefficients have been reported
83 at room temperature for the reaction of NO₃ with five C₅-C₈ aldehydes, *E*-2-pentenal, *E*-2-
84 hexenal, *E*-2-heptenal, *Z*-4-heptenal and *E*-2-octenal using different techniques. Again in
85 some cases the reactions were also studied as a function of temperature.^{6,7} Rate coefficients
86 for the reaction of Cl with C₅-C₇ 2-enals (*E*-2-pentenal, *E*-2-hexenal, *E*-2-heptenal) have
87 been reported in a single study by Rodriguez et al.¹¹ who performed the measurements at
88 298 K using a relative kinetic method.

89 With regard to the ozonolysis of >C₄ unsaturated aldehydes, which is the subject of this
90 study, Sato et al.¹² have determined rate coefficients at 298 K for the reaction of O₃ with
91 three pentenals, *E*-2-pentenal, 3-methyl-2-butenal and *E*-2-methyl-2-butenal, using the
92 relative kinetic method. Grosjean et al.¹³ and Atkinson et al.¹⁴ have both measured the rate
93 coefficient for the reaction of O₃ with *E*-2-hexenal at room temperature using absolute and
94 relative methods, respectively.

95 Since unsaturated aldehydes are released to the atmosphere in substantial amounts from
96 combustion and vegetation and there are not many studies on the ozonolysis of these
97 compounds, the motivation of this work was to investigate the ozonolysis of some longer
98 carbon chain unsaturated aldehydes. The organic compounds studied in this work *trans*-2-
99 heptenal, *trans*-2-octenal, *trans*-2-nonenal are biogenic aldehydes emitted from different
100 types of vegetation¹⁵⁻¹⁷. As part of a systematic study on the kinetics of the atmospheric
101 reactions of different unsaturated oxygenated VOCs, we report in this study rate
102 coefficients for the reactions of O₃ molecules with the aforementioned aldehydes at 298 K

103 and atmospheric pressure of synthetic air in a large volume photoreactor using the relative
104 kinetic method:

105

109

110 To the best of our knowledge rate coefficients of the above reactions have not been
111 previously reported and this work, therefore, represents the first kinetic study of the
112 reactions.

113 Additionally, the reactivity of the unsaturated aldehydes studied in this work together with
114 other unsaturated VOCs toward O₃ molecules has been correlated i) with the reactivity of
115 the same VOCs toward OH radicals and ii) with the energies of the Highest Occupied
116 Molecular Orbit (HOMO) of the unsaturated compounds. Tropospheric lifetimes for the
117 studied aldehydes have been calculated and potential atmospheric implications assessed.

118 The kinetic data and correlations presented here help to improve our understanding of the
119 atmospheric oxidation mechanisms of aldehydes. They also help in assessments of the
120 potential contributions of the compounds to the oxidizing capacity of the tropospheric and
121 photochemical smog and SOA formation.

122

123

124

125

126

127 **Experimental section**

128

129 All the experiments were performed in a 1080 L chamber at (298 ± 2) K in 990 ± 10 mbar
130 of synthetic air. The chamber is composed of a cylindrical quartz vessel (total length 6.2 m
131 and an inner diameter of 0.47 m) closed at both ends by aluminum end flanges. The metal
132 flanges contain ports for the introduction of bath gases and reactants into the chamber. A
133 magnetically coupled Teflon mixing fan is mounted inside the chamber to ensure
134 homogeneous mixing of the reactants. The reactor can be evacuated by a pumping system
135 consisting of a turbomolecular pump backed by a double stage rotary fore pump to 10^{-3}
136 Torr. A White-type mirror system mounted internally in the chamber and coupled to a
137 FTIR spectrometer Nicolet Nexus equipped with a liquid nitrogen cooled mercury–
138 cadmium–telluride (MCT) detector enables ‘in situ’ monitoring of the reactants in the
139 infrared range 4000–700 cm. The White mirror system was operated with the total optical
140 absorption path length set to 484.7 m and infrared spectra were recorded with a spectral
141 resolution of 1cm^{-1} , 100 interferograms were co-added per spectrum over a period of more
142 than 1 min and 15 such spectra were recorded per experiment. The chamber is described in
143 greater detail elsewhere.^{18,19} Ozone was added stepwise to mixtures containing the
144 unsaturated aldehydes and reference compound. An electrical discharge in a flow of pure
145 oxygen was used to generate ozone. The initial concentrations of reactants in (ppmV) were
146 approximately: 0.9 for *trans*-2-heptenal; 0.8 for *trans*-2-octenal; 0.7 for *trans*-2-nonenal;
147 3.0 for ethene; 4.0 for 1,3-butadiene; 0.5 for vinyl propionate and 6-9 for ozone. The
148 reactants were monitored at the following infrared frequencies (cm^{-1}): *trans*-2-heptenal at

149 3077-2657; *trans*-2-octenal at 3000-2650; *trans*-2-nonenal at 3011-2649; ethene at 949;
150 1,3-butadiene at 908 and vinyl propionate at 1170. Typical IR spectra of the kinetics
151 experiments performed for the reactions of O₃ with *trans*-2-heptenal, *trans*-2-octenal and
152 *trans*-2-nonenal are presented in the Supplementary Information (SI) as Figure S1, Figure
153 S2 and Figure S3, respectively. In addition, the concentration-time profiles for the three
154 unsaturated aldehydes (*trans*-2-heptenal, *trans*-2-octenal and *trans*-2-nonenal) are
155 presented as Figures S4, S5 and S6, respectively in the SI.

156

157 **Results and discussion**

158

159 Rate coefficients for the reactions of the aldehydes with O₃ were determined using the
160 relative rate method in which the rates of decay of the aldehydes were monitored relative to
161 the decay of reference compounds.

162

165 If the unsaturated aldehydes and reference organics are removed solely by reaction with O₃
166 molecules according to equation (4) and (5) then equation (I) is valid:

167

$$\ln \left\{ \frac{[\text{aldehyde}]_0}{[\text{aldehyde}]_t} \right\} = \frac{k_1}{k_2} \ln \left\{ \frac{[\text{reference}]_0}{[\text{reference}]_t} \right\} \quad (I)$$

170 where [aldehyde]₀, [reference]₀, [aldehyde]_t and [reference]_t are the concentrations of the
171 unsaturated aldehyde compound under study and the reference compound at times t = 0 and
172 t, respectively, and k₁ and k₂ are the rate coefficients of reactions (4) and (5) respectively.

173 Experiments were carried out to assess the loss of the unsaturated aldehyde and reference
174 compound through deposition to the reactor wall. The wall losses of the unsaturated
175 aldehyde and reference compound before the addition of O₃ were found to be negligible.
176 Three experiments were performed per reference compound and two reference compounds
177 were employed for each of the investigated aldehydes. Data plotted in the form of Eq. (I)
178 are presented in Figures 1-3 and the values of the rate coefficient k_1/k_2 are summarized in
179 Table 1 together with the absolute values of the rate coefficients for the reactions of O₃ with
180 the aldehydes calculated from the k_1/k_2 ratios. The error bars in Figures 1-3 are the 2σ
181 statistical errors from the scatter in the plots. The rate coefficients for the reactions of O₃
182 molecules with the unsaturated aldehydes were placed on an absolute basis using the
183 following values for the reference reactions at 298 K: O₃ + ethene $(1.37 \pm 0.08) \times 10^{-18} \text{ cm}^3$
184 $\text{molecule}^{-1} \text{ s}^{-1}$ ²⁰; O₃ + 1,3-butadiene $(6.3 \pm 0.4) \times 10^{-18} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ ²⁰ and O₃ + vinyl
185 propionate $(5.3 \pm 1.3) \times 10^{-18} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$.²¹
186 The errors quoted for the rate coefficients for the reactions of O₃ with the aldehydes in
187 Table 1 are a combination of the 2σ statistical errors from the linear regression analyses of
188 the plots plus the corresponding error of the reference reaction rate coefficient. As can be
189 seen from Table 1 there is good agreement between the rate coefficients obtained for the
190 reaction of O₃ with the aldehydes using two different reference compounds. Because of this
191 good agreement, we prefer to give final rate coefficients for the reactions which are an
192 average of all the determinations, i.e.

193

194
$$k_{(\text{O}_3 + \text{trans-2-heptenal})} = (2.47 \pm 0.73) \times 10^{-18} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$$

195 $k_{(\text{O}_3 + \text{trans-2-octenal})} = (2.37 \pm 0.68) \times 10^{-18} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$

196 $k_{(\text{O}_3 + \text{trans-2-nonenal})} = (2.05 \pm 0.20) \times 10^{-18} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$

197

198 It is well established that the ozonolysis of alkenes produces OH radicals which can
199 interfere with relative kinetic studies of the type presented here. To minimize this inference
200 an organic compound or CO is often added to the system to scavenge the OH radicals. The
201 rate coefficients for the reactions of the unsaturated aldehydes under investigation in this
202 study are very high, thus in order to effectively scavenge any OH radicals produced during
203 the ozonolysis reaction high concentrations of a scavenger would be necessary. Since such
204 high concentrations of the scavenger in the reaction system would render monitoring of the
205 reactants in the infrared impossible, the experiments have been performed in the absence of
206 a scavenger. We have obtained values of the rate coefficients for the reactions of O₃ with
207 the aldehydes using two reference compounds which are in excellent agreement with one
208 another. Since the rate coefficients for the reactions of O₃ with the reference compounds
209 differ by a factor of approximately 4 and their rate coefficients with OH are all quite
210 different we argue that any influence by OH in the reaction systems can not be very
211 significant.

212 Since all of the hydrocarbons in the system will react with OH it would appear that in the
213 systems investigated any interference by OH, that might possibly be occurring, is largely
214 self-compensating. However, it is still important to keep in mind when making rate
215 coefficient comparisons that the present values were determined in the absence of an OH
216 radical scavenger.

217 The rate coefficients values obtained for the three reactions studied are very similar and
218 within the error limits can be considered the same. The rate coefficients for the reactions of
219 ozone with the three aldehydes have been estimated using the US EPA AOPWIN
220 program²² which is based upon the structure-activity relationship (SAR) method described
221 in Kwok and Atkinson.²³ This estimation method predicts a rate coefficient value of $1.82 \times$
222 $10^{-18} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ for all three of the unsaturated aldehydes which is lower than
223 experimental values reported here by approximately 35% for *trans*-2-heptenal, 30% for
224 *trans*-2-octenal and 13% for *trans*-2-nonenal. This agreement is quite acceptable
225 considering the uncertainties in the rate coefficient determinations.

226 The rate coefficient of $(2.0 \pm 1.0) \times 10^{-18} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ reported by Atkinson et al.¹⁴ for
227 the reaction of O₃ with *trans*-2-hexenal is very similar, within the error limits, to the rate
228 coefficients determined in this work for the reactions of O₃ with *trans*-2-heptenal, *trans*-2-
229 octenal and *trans*-2-nonenal. This similarity in the reactivity for $\geq \text{C6}$ unsaturated-2-enals
230 toward O₃ supports that above C6 further increases in the alkyl chain length of the aldehyde
231 has a negligible effect on the magnitude of the electron donation to the double bond.

232 Rate coefficients for the addition of OH and NO₃ radicals, Cl atoms and O₃ molecules to
233 alkenes and unsaturated VOCs has been shown previously to correlate with the energy of
234 the HOMO of the different VOCs.^{24,25,26} The electron density in the π -bond that is attacked
235 by the O₃ molecule should be reflected in the energy of the highest occupied molecular
236 orbital (E_{HOMO}) with the lowest negative value being expected for the compound with the
237 largest rate coefficient. To contribute to and extend the correlations reported previously for
238 the rate coefficients of OH and Cl reactions with E_{HOMO} energies,²⁷ a new correlation for the

239 ozonolysis of different unsaturated VOCs has been determined using the Gaussian 03
240 package²⁸. The geometry optimizations and initial values of the energies were obtained at
241 the B3LYP level with a 6-311G(d,p) bases set. The E_{HOMO} calculated for the unsaturated
242 aldehydes and the other unsaturated VOCs are listed in Table 2. Figure 4 shows a plot of
243 the natural logarithms of the O_3 rate coefficients plotted as a function of the calculated
244 E_{HOMO} in eV. A linear relationship is obtained. The linear relationship in Figure 4 is well
245 described by:

$$246 \quad -\ln k_{\text{O}_3} (\text{cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}) = (9.52 \pm 1.12) (-E_{\text{HOMO}}) + (26.50 \pm 2.35), \quad r^2=0.97 \quad (\text{II})$$

247 The quality of the correlation is such that it can be used for reasonable estimations of rate
248 coefficients for the reactions of O_3 molecules with other unsaturated VOCs where data does
249 not yet exist.

250 In addition, we present for the first time, a correlation between k_{OH} and k_{O_3} for a wide range
251 of different unsaturated VOCs. The rate coefficients for the reactions of different
252 unsaturated VOCs with O_3 molecules and OH radicals at 298 K are listed in Table 1. The
253 correlation obtained between the rate coefficients for the reactions of O_3 molecules with a
254 given alkene or unsaturated VOC and those for the corresponding reactions with OH
255 radicals is shown in Figure 5. A reasonable correlation is obtained and a least-squares
256 treatment of the data points in Figure 5 yields the following expression (with the rate
257 coefficients in units of $\text{cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$):

$$258 \quad \log k_{\text{OH}} = 0.16 \log k_{\text{O}_3} - 7.55, \quad r^2=0.95 \quad (\text{III})$$

259 The quality of this correlation is also such that it can be used to make reasonable
260 estimations of rate coefficients for reactions of O₃ molecules with other unsaturated VOCs
261 where data does not yet exist.

262 The atmospheric lifetime of the studied aldehydes with respect to reaction with the main
263 tropospheric oxidants can be estimated using the expression:

$$\tau_x = \frac{1}{k_x \times [X]} \quad (\text{IV})$$

265 where X= O₃, OH, NO₃ or Cl and k_x is the rate coefficient of the aldehyde with the oxidant
266 X, The following typical tropospheric oxidant concentrations have been used in calculating
267 the lifetimes: [O₃] = 7×10¹¹ molecule cm⁻³ ²⁹; [OH] = 2×10⁶ radical cm⁻³ ³⁰; [Cl] = 1×10⁴
268 atom cm⁻³ ³¹ and [NO₃] = 5×10⁸ radical cm⁻³ ³². The atmospheric lifetimes for the reaction
269 of the aldehydes with ozone and the other oxidants, where data are available, are presented
270 in Table 3. The lifetimes show that the unsaturated aldehydes will be degraded by reaction
271 with NO₃ radical during the night and with OH radicals during the day. At the levels of O₃
272 typically present in the troposphere, decay of the unsaturated aldehyde with O₃ will be
273 insignificant but could potentially be of some importance during episodes of elevated O₃
274 levels. Wet and dry deposition will be a minor loss process for the aldehydes since they are
275 highly volatile and sparingly soluble in water.

276 Degradation of longer chain aldehydes constitutes a significant source of aldehydes
277 containing less carbon atoms than the precursor. In the presence of OH, NO₃, O₃ longer
278 chain unsaturated aldehyde will probably be degraded to much shorter chain aldehydes,
279 which have longer lifetimes and can contribute effectively to tropospheric ozone and SOA

280 formation. In addition, longer chain aldehydes in the course of their degradation can
281 undergo isomerization reactions forming carbonyl compounds which in further oxidation
282 reactions can form thermally stable PAN type compounds.

283 For the reactions studied in this work we expect, based on existing ozonolysis studies, that
284 pentanal, hexanal and heptanal will be major reaction products from the reactions of O₃
285 with *trans*-2-heptenal, *trans*-2-octenal and *trans*-2-nonenal, respectively. Glyoxal will also
286 be a major reaction product for all three aldehydes. However, the exact nature and yields of
287 the products formed in the ozonolysis of the unsaturated aldehydes studied here still
288 remains to be elucidated.

448

449 **Figure 1.** Plot of the kinetic data for the reaction of O₃ molecules with *trans*-2-heptenal
450 measured relative to ethene (□) and vinyl propionate (○) at (298 ± 2) K and atmospheric
451 pressure of air.

452

453 **Figure 2.** Plot of the kinetic data for the reaction of O₃ molecules with *trans*-2-octenal
454 measured relative to ethene (□) and vinyl propionate (○) at (298 ± 2) K and atmospheric
455 pressure of air.

456

457 **Figure 3.** Plot of the kinetic data for the reaction of O₃ molecules with *trans*-2-nonenal
458 measured relative to ethene (□) and 1,3-butadiene (Δ) at (298 ± 2) K and atmospheric
459 pressure of air.

460

461 **Figure 4.** Correlation of ln k_{O₃} (cm³ molecule⁻¹ s⁻¹) against E_{HOMO} calculated using the
462 Gaussian 3.0 package B3LYP/6-311G(d,p) for the reactions of volatile organic compounds
463 with ozone. The numbers correspond to the compounds listed in Table 2 and the filled
464 circles highlight the aldehydes, *trans*-2-heptenal, *trans*-2-octenal and *trans*-2-nonenal,
465 studied in this work.

466

467 **Figure 5.** Linear free energy plot of $\log k_{\text{OH}}$ against $\log k_{\text{O}_3}$ at room temperature for a series
 468 of unsaturated volatile organic compounds. The numbers correspond to the compounds
 469 listed in Table 2 and the filled circles highlight the aldehydes, *trans*-2-heptenal, *trans*-2-
 470 octenal and *trans*-2-nonenal, studied in this work.

471

472

473

474 **Table 1**

475 Rate coefficient ratios k_1/k_2 and rate coefficients for the reactions of ozone with
 476 *trans*-2-heptenal, *trans*-2-octenal and *trans*-2-nonenal at (298 ± 2) K in (990 ± 10) mbar of
 477 air.

478

Unsaturated aldehyde	Reference	k_1/k_2	$k_{(\text{O}_3+\text{aldehyde})} \times 10^{18}$ ($\text{cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$)
