### Abstract

In educational research, the availability of a validated version of an original instrument in a different language offers the possibility for valid measurements obtained within the specific educational context and in addition it provides the opportunity for valid cross-cultural comparisons. The present study aimed to adapt the Science Motivation Questionnaire II (SMQ II) for application into a different cultural context (Greece), a different age group (secondary school students) and with a focus on chemistry learning. Subsequently, the Greek version of Chemistry Motivation Questionnaire II (Greek CMQ II) was used in order to investigate Greek secondary school students' motivation to learn chemistry for the first time. The sample consisted of 330 secondary school students (163 boys - 167 girls) of which 146 were in lower secondary school (14-15 y) and 184 were in upper secondary school (16-17 y). Confirmatory factor analyses provided evidence for the validity of Greek CMQ II, as well as for configural, metric and scalar invariance, thus allowing meaningful comparisons between groups. The five motivation components of the original instrument namely grade motivation, career motivation, intrinsic motivation, self-efficacy, and self-determination were confirmed. Gender-based comparisons showed that girls had higher self-determination relative to the boys irrespective of age group. In addition, girls in lower secondary school had higher career and intrinsic motivation relative to the boys of the same age group. Age-based comparisons showed that lower secondary school students had higher grade motivation relative to upper secondary school students.

8 **Introduction**  
9

10 The study of the role of motivation in learning science is constantly gaining the  
11 attention of science education researchers (Koballa and Glynn, 2007). In recent  
12 science education literature, motivation is considered as “a complex multidimensional  
13 construct that interacts with cognition to influence learning” (Taasobshirazi and  
14 Sinatra, 2011, p. 904). Both cognitive and motivational learner characteristics interact  
15 within a specific learning environment in order to support or hinder conceptual  
16 change (Dole and Sinatra, 1998). Pintrich and his colleagues (1993) have adopted four  
17 general motivational constructs (namely goals, values, self-efficacy, and control  
18 beliefs) as potential mediators of the learner’s conceptual change and suggested that  
19 they may influence science learning both in the short term and over longer periods of  
20 time as well. In addition, a series of contextual factors, including the classroom  
21 environment, the teacher, the nature of academic tasks, and the assessment processes  
22 have been proposed to moderate the interactions between motivational constructs and  
23 science learning (Pintrich *et al.*, 1993).

43 The complex multidimensional nature of motivation has been brought out via the use  
44 of social cognitive theory which has been systematically employed over the last  
45 fifteen years in order to explain human learning and motivation in terms of reciprocal  
46 interactions involving personal characteristics (e.g., intrinsic motivation, self-efficacy,  
47 and self-determination), environmental contexts (e.g., high school), and behaviour  
48 (e.g., enrolling in advanced science or chemistry courses) (Bandura, 2001; Pintrich,  
49  
50  
51  
52

60  
2003).

1  
2  
3 Concentrating on the role of motivation in learning science and more specifically  
4 chemistry as a distinct science subject, a recent study by Zusho *et al.* (2003) provided  
5 evidence that students' beliefs in relation with self-efficacy and task-value are  
6 significant predictors of their performance in chemistry. The same researchers also  
7 reported that students' judgments of their confidence to do well in the chemistry class  
8 decreased over time, and as a result students beliefs about the importance and/or  
9 usefulness of the chemistry course tended to deteriorate as well. Moreover, evidence  
10 has been provided that poor motivation to learn chemistry often leads students to turn  
11 away from advanced chemistry studies and chemistry related careers (Salta *et al.*,  
12 2012).

13  
14  
15 The constantly increasing interest for the study of students' motivation to learn  
16 science has triggered the development of several instruments for measuring students'  
17 motivation based on different theoretical perspectives. From the perspective of social  
18 cognitive theory, Glynn and his colleagues (2011) have developed and evaluated the  
19 Science Motivation Questionnaire II (SMQ II). This instrument has been found to be a  
20 reliable and valid tool which leads to the assessment of the following five components  
21 of students' motivation to learn science in college courses in USA (Glynn *et al.*,  
22 2011): intrinsic motivation, self-determination, self-efficacy, career motivation, and  
23 grade motivation.

24  
25  
26 The main purpose of the present study has been the adaptation and validation of the  
27 chemistry specific version of SMQ II (ie the Chemistry Motivation Questionnaire II  
28 or briefly CMQ II) with Greek students (thus producing the Greek CMQ II). The  
29 rationale behind this work lies on the need for the availability of valid measurements  
30 which will subsequently allow for cross-cultural comparisons in order to explore the  
31 proposed influence of the cultural context on the motivational constructs (Pintrich,  
32  
33  
34  
35

2003). Besides the different cultural context (Greece relative to USA), two additional factors are changed in the current study relative to the original work of Glynn *et al.* (2011): a) students belong to a younger age group and different educational level (secondary school relative to college) and b) the focus is on measuring motivation to learn a specific science subject which is chemistry.

Thus, the specific research questions that have guided this study can be summarized as follows:

- 1) How valid is the Greek version of the “Chemistry Motivation Questionnaire II” (Greek CMQ II) for measuring secondary school students’ motivation to learn chemistry?

Subsequently, if Greek CMQ II proves to be valid,

- 2) Which are the motivational characteristics of Greek secondary school students to learn chemistry?
- 3) What are the differences in motivation to learn chemistry between Greek lower and upper secondary school students?
- 4) What are the differences in motivation to learn chemistry between Greek male and female secondary students?

### **Theoretical Framework**

The term “motivation” has been defined “as the attribute that ‘moves’ us to do or not do something” (Gredler, 2001 as cited in Broussard and Garrison, 2004, p. 106). In education, motivation to learn is broadly considered as “the internal state that arouses, directs, and sustains students’ behaviour” (Koballa and Glynn, 2007, p. 85). According to Brophy (1983) “motivation to learn refers to the enduring disposition of students to enjoy the process of learning and take pride in the outcomes of experience

1  
2  
3 involving knowledge acquisition or skill development” (p. 200). Hence, modern  
4 theories of motivation focus mainly “on the relation of beliefs, values, and goals with  
5  
6 action” (Eccles and Wigfield, 2002, p. 110).  
7  
8

9  
10 Research on motivation associated with academic achievement and/or development  
11 has been conducted via different theoretical perspectives and has led to the  
12 development of an extensive motivation terminology (Murphy and Alexander, 2000).  
13  
14 In fact, theorists have indicated the need for theoretical integration in the domain  
15 (Eccles and Wigfield, 2002). The main theoretical perspectives that have been  
16 employed in the study and conceptualization of motivation can be briefly summarized  
17 as follows.  
18  
19

20 Achievement goal theory or simply goal theory (Ames, 1992; Blumenfeld, 1992)  
21 relates students’ goals to their achievement behaviour. The main idea in this  
22 perspective is the “goal orientations” that refer to students’ beliefs about the purpose  
23 of engaging in achievement-related behaviour.  
24  
25

26 Self-determination theory (Deci and Ryan, 2000) postulated that an understanding of  
27 human motivation requires a consideration of innate psychological needs for  
28 competence, autonomy and relatedness. As reviewed in Deci and Ryan (2000), a  
29 social context which supports these three needs tends to enhance intrinsic motivation  
30 and facilitate the internalization of extrinsic motivation. Subsequently, enhanced  
31 motivation seems to be associated with positive affective experiences, and high-  
32 quality performance.  
33  
34

35 The theoretical concept of interest has attracted researchers’ attention over the past  
36 few years (Hidi & Harackiewicz, 2001; Schiefele, 1999), and has been proposed to be  
37 connected with intrinsic motivation to learn by educational psychologists (Koballa  
38 and Glynn, 2007). A distinction between individual and situational interest is typically  
39  
40  
41  
42  
43  
44  
45  
46  
47  
48

54  
55  
56  
57  
58  
59  
60

1  
2  
3 made. Particularly, individual interest is considered as a relatively stable orientation  
4 towards certain domains in contrast with situational interest that is an emotional state  
5 aroused by specific features of a task (Hidi and Renninger, 2006). Much research on  
6 the relation between individual interest and learning has been conducted (Renninger  
7 *et al.*, 2002; Schiefele, 1999). An important finding was the stronger relationship  
8 between interest and deep- learning than with rote learning (Schiefele, 1999).  
9

10  
11 Finally, the theoretical perspective of the social cognitive theory, originally developed  
12 by Bandura (1986) and extended by the same and other researchers (Bandura, 2001;  
13 Pajares and Schunk, 2001; Pintrich, 2003), conceptualizes the process of learning via  
14 a series of reciprocal interactions among personal, behavioural and  
15 social/environmental factors. Within the framework of social cognitive theory,  
16 Pintrich and his colleagues (1993) proposed a conceptual change model for describing  
17 students' learning and postulated that the cognitive and motivational constructs  
18 influence each other and at the same time they are influenced by the social context. In  
19 turn, both cognitive and motivational constructs are assumed to influence students'  
20 involvement with their learning and, consequently, achievement outcomes (Pintrich,  
21 2000).  
22

23  
24 As also noted in the Introduction, the social cognitive theory conceptualizes  
25 motivation to learn as a multidimensional construct which is therefore comprised of  
26 several components (also referred in Glynn *et al.* (2011) as “types and attributes of  
27 motivation”). Many motivational components linked to learning science have been  
28 studied extensively and reviewed in Glynn and Koballa (2006), Koballa and Glynn  
29 (2007), Pintrich (2003), and Schunk *et al.* (2008). Examples of these components are  
30 intrinsic motivation, which involves the inherent satisfaction in learning science for its  
31 own sake (e.g., Eccles *et al.*, 2006); extrinsic motivation, which involves learning

1  
2  
3 science as a means to a tangible end, such as a career or a grade (e.g., Mazlo *et al.*,  
4  
5  
6 2002); self-determination, which refers to the control students believe they have over  
7  
8 their learning of science (e.g., Black and Deci, 2000); and self-efficacy, which refers  
9  
10 to students' belief that they can achieve well in science (e.g., Lawson *et al.*, 2007).  
11  
12 The above examples of motivation components are also included in the list of 20  
13  
14 motivation terms proposed to be relevant to academic achievement and motivation  
15  
16 (Murphy and Alexander, 2000). This "corpus" of terms contains motivation  
17  
18 components associated with all four theoretical perspectives of motivation we referred  
19  
20 to above.  
21  
22  
23

24  
25 In the following part of this theoretical section a brief overview of the literature on  
26  
27 motivation to learn science with a focus on chemistry will be made. With regard to  
28  
29 students' motivational characteristics toward a specific science domain, there is  
30  
31 evidence that even in pre-primary school, children express some differences in their  
32  
33 motivation toward different science disciplines (Mantzicopoulos *et al.*, 2008).  
34  
35 Focusing on chemistry learning, there exist some studies which have attempted to  
36  
37 examine how it may be influenced by students' motivation (Aydin and Uzuntiryaki,  
38  
39 2009; Black and Deci, 2000; Feng and Tuan, 2005; Jurišević *et al.*, 2008; Mazlo *et*  
40  
41 *al.*, 2002; Scherer, 2013; Taasoobshirazi and Glynn, 2009; Zusho *et al.*, 2003). Black  
42  
43 and Deci (2000) applied self-determination theory to investigate the effects of  
44  
45 students' course-specific self-regulation and their perceptions of their instructors'  
46  
47 autonomy support on adjustment and academic performance in a college-level organic  
48  
49 chemistry course. Their results have shown that the students' perceived instructor  
50  
51 autonomy support is related to positive adjustment and to increased students'  
52  
53 autonomy as the semester progresses, which is in turn related to better performance.  
54  
55  
56  
57  
58  
59  
60 Zusho and his colleagues (2003) evidenced on one hand an overall decline in college

1  
2  
3 students' motivational levels over time and on the other an increase in students' use of  
4 organizational and self-regulatory strategies. A diversity of trends was found which  
5 were shown to be dependent on students' achievement levels. Finally, the relation of  
6 motivation to achievement was evidenced via the identification of two motivational  
7 components, namely self-efficacy and task value, as "best predictors of final course  
8 performance even after controlling for prior achievement" (Zusho *et al.*, 2003, p.  
9 1081).

10  
11  
12  
13  
14  
15  
16  
17  
18  
19  
20 Research conducted by Juriševič and her colleagues (2008) showed that Slovene first  
21 year pre-service primary school student teachers (18.5 years old) are more or less  
22 equally motivated for chemistry as for any other subject, but their intrinsic motivation  
23 decreases as the level of abstraction increases. It has been similarly established that  
24 among the three levels of chemistry learning—namely, macroscopic, submicroscopic,  
25 and symbolic—students were the least motivated to study concepts at the symbolic  
26 level (Juriševič *et al.*, 2008). Taasobshirazi and Glynn (2009) found that college  
27 students' self-efficacy influenced strategy use and chemistry problem solving.  
28 Students with relatively high chemistry self-efficacy tended to use a working-forward  
29 strategy and solve problems successfully while students with relatively low chemistry  
30 self-efficacy tended to use a working-backward strategy and solve the problems  
31 incorrectly. Their findings are consistent with other studies conducted on students'  
32 chemistry self-efficacy, such as those of Zusho *et al.* (2003) and Schraw *et al.* (2005).  
33  
34  
35  
36  
37  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60  
Moreover, Scherer (2013) has provided evidence for the empirical distinction between  
the motivation components of self-concept and self-efficacy within the domain of  
chemistry. By using data collected by 459 German high-school students (mean age  
16.6 years), he found that students' perceptions of themselves within the academic  
environment (academic self-concept) are not the same with their perceptions about

1  
2  
3 their ability to master given tasks or develop specific competences (academic self-  
4 efficacy) within the domain of chemistry. However, his results indicated that the two  
5  
6 constructs affect each other.  
7  
8  
9

10  
11  
12 *Cultural and contextual effects in motivation to learn science and chemistry*  
13

14  
15 One of the aims of social cognitive theory is exploring the influence that different  
16  
17 contextual and cultural practices may have on students' motivation. According to  
18  
19 Brophy (2004), the psychology of motivation that has been developed by studies in  
20  
21 western countries is reflective of a common human condition and thus equally  
22  
23 applicable everywhere. However, comparative research has identified interesting  
24  
25 contrasts between nations and world regions. For example, Hufton *et al.* (2002) found  
26  
27 that Russian adolescents showed patterns of school-related motivation that contrasted  
28  
29 in several respects with those displayed by American and British adolescents.  
30  
31 Particularly, Russian students tend to maintain task engagement even though their  
32  
33 teachers are short on praise and overly persistent on correction. It is suggested that  
34  
35 this pattern reflects a pervasive Russian cultural value on becoming an educated  
36  
37 person.  
38  
39

40  
41  
42 Perhaps the most significant cultural differences have been observed between people  
43  
44 from western nations (e.g., the United States and Western Europe) and people from  
45  
46 East Asia (e.g., China, Korea, and Japan). Studies have shown that in the former  
47  
48 countries people display a more individualistic attitude and their self-concepts  
49  
50 emphasize uniqueness and independence from others. On the other hand, people from  
51  
52 East Asia display a more collectivistic attitude with self-concepts which are  
53  
54 interdependent (Boekaerts, 1998; Fiske *et al.*, 1998). These general differences lead to  
55  
56 differences on more specific motivational aspects. In attributing behaviour to causes,  
57  
58  
59  
60

1  
2  
3 for example, East Asians tend to make fewer references to personal dispositions but  
4 more references to situational factors than westerners do (Choi *et al.*, 1999; Krull *et*  
5 *al.*, 1999). Other studies have indicated that East Asians also tend to be more  
6 comfortable setting up their personal agendas by taking into account those of their  
7 families or groups. For example, East Asian (but not American) students display  
8 increased benefit perception of goal achievement when they pursue goals in order to  
9 please others (e.g. parents or friends) (Oishi and Diener, 2001). Similarly, East Asian  
10 students seem to show higher levels of intrinsic motivation relative to American  
11 students “when choices are made for them by trusted significant others” rather “than  
12 when they make the choices themselves” (Iyengar and Lepper, 1999).

13  
14 Moreover, also within a specific cultural context, differences have been observed in  
15 students’ motivational patterns depending on age, gender and family environment.  
16 Different grade levels present somewhat different motivational challenges because of  
17 age-related changes in students’ motivational patterns. Thus, there is evidence that the  
18 enthusiastic start of schooling by most students is followed by gradual decrease on  
19 measures of intrinsic motivation, curiosity and school-related attitudes. (Gentry *et al.*,  
20 2002; Gottfried *et al.*, 2001; Wigfield and Eccles, 2002). Potvin *et al.* (2009)  
21 suggested that the first 2 years of high school may be a critical period when students  
22 turn toward or away from a science career path; whereas Bryan *et al.* (2011) argued  
23 that for those students who turn towards a science career path the last 2 years of high  
24 school may be a critical period for motivation to learn particular areas/disciplines of  
25 science.

26  
27 As students develop in our society, they are exposed to gender role socialization.  
28 Thus, certain family and social roles, occupations, personal attributes, and ways of  
29 dressing and behaving are considered primarily feminine, while others primarily  
30  
31  
32

2  
3 masculine. Most students have certain individuals they encounter in their personal  
4 lives and in the media as role models. The behaviour expressed by the students  
5 reflects the messages they receive from their parents and peers (and even sometimes  
6 their teachers) (Li, 1999; Tenenbaum and Leaper, 2003). To the extent at which a  
7 specific school activity is associated primarily with one gender, students' attitudes and  
8 expectations are likely to be affected.

9  
10 Focusing on the role of gender on students' motivation to learn science, recent  
11 research by Glynn *et al.* (2011) has provided evidence for a gender effect favouring  
12 college male students with regard to a specific motivational construct, namely self-  
13 efficacy. On the other hand, a study conducted among upper secondary school  
14 students and in a cross-cultural context which included four countries namely  
15 Malaysia, Slovenia, Switzerland, and Turkey revealed more complicated relationships  
16 between gender and motivation (Zeyer *et al.*, 2013).

### 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 32 33 34 35 36 37 *Measuring students' motivational constructs*

38 A motivational construct generally corresponds to a latent variable which is a  
39 presumed explanatory variable to reflect a continuum that is not directly observable  
40 (Kline, 2011). Thus a construct may be assessed only indirectly; this is achieved via  
41 measuring certain items which indicate empirically how the specific construct is  
42 conceptualized by the subject. Students' conceptualizations are important since they  
43 tend to influence their actions (McGinnis *et al.*, 2002; Scott *et al.*, 2007).

Recently, several studies have focused on developing students' motivation scales to learn science (Glynn and Koballa, 2006; Glynn *et al.*, 2009; 2011; Tuan *et al.*, 2005; Velayutham *et al.*, 2011). A Students' Motivation towards Science Learning (SMTSL) questionnaire was developed by Tuan and her colleagues (2005) and was

1  
2  
3 validated with junior high school students from central Taiwan. The researchers  
4 identified six motivational constructs: self-efficacy, active learning strategies, science  
5 learning value, performance goal, achievement goal, and learning environment  
6 stimulation. The SMTSL questionnaire has been used as a tool for measurement of  
7 change in students' learning motives after the implementation of specific activities in  
8 a chemistry course (Feng and Tuan, 2005). Recently, the SMTSL questionnaire has  
9 been adapted in the Greek language and has been used in undergraduate student  
10 teachers with reference to physics learning (Dermitzaki *et al.*, 2013). Nonetheless, the  
11 developers have annotated the conceptualization and measurement of some constructs  
12 as ambiguous and not theoretically sound (Tuan *et al.*, 2005). Another instrument, the  
13 Students' Adaptive Learning Engagement in Science questionnaire was developed by  
14 Velayutham and her colleagues (2011) based on theoretical and research  
15 underpinnings. The validation process resulted on four constructs which included goal  
16 orientation, task value, self-efficacy, and self-regulation. The researchers reported  
17 evidence for strong construct validity of the scales, by testing them on Australian  
18 lower secondary students (Velayutham *et al.*, 2011). Another scale designated as the  
19 "High School Chemistry Self-Efficacy Scale" was developed and validated by Aydin  
20 and Uzuntiryaki (2009) in order to measure Turkish high school students' self-  
21 efficacy from the perspectives of cognitive and laboratory competencies.

Glynn and his colleagues focused on those motivational components/constructs that  
influence self-regulatory learning to develop and validate the Science Motivation  
Questionnaire II (SMQ II) (Glynn and Koballa, 2006; Glynn *et al.*, 2007; 2009;  
2011). According to the developers, the items of SMQ II were designed to serve as  
empirical indicators of components of students' motivation to learn science in college  
courses. The following five motivation components (scales) are included in the final

1  
2  
3 version of SMQ II (Glynn *et al.*, 2011), each one comprised of 5 items, and constitute  
4 the working model of motivation in the present work as well: intrinsic motivation,  
5 self-determination, self-efficacy, career motivation, and grade motivation. The scales  
6 were found to be useful in assessing the motivation of both science and non-science  
7 majors. The motivation scales of SMQ II were shown to be positively related, with  
8 intrinsic and career motivation exhibiting the strongest relation. In addition, the scales  
9 were shown to be related with students' marks, with strongest relation exhibited by  
10 self-efficacy.

### 27 **The Present Study**

28  
29 In regard with research on motivation in school settings, most investigations have  
30 been conducted in the mathematics and science domains. Moreover, the majority of  
31 these studies have been undertaken with college students. Therefore, both from an  
32 academic as well as from a practical point of view (eg. for use in the educational  
33 policy decision making process), it is important to investigate the motivation of  
34 secondary school students to learn science and particularly chemistry. In addition,  
35 there is a need to accurately examine how the motivational constructs might be  
36 moderated by different cultural/educational contexts. The availability of valid  
37 instruments for measuring motivation is a vital necessary requirement in order to  
38 engage in such a demanding research task. Hence, we anticipate that the investigation  
39 of motivation to learn chemistry among Greek secondary school students will provide  
40 a valuable contribution to various aspects of research related with motivation. Finally,  
41 it is important to note that in Greece there has been so far no systematic study which  
42 aims directly at measuring students' motivation to learn chemistry. A measurement of  
43

1  
2  
3 upper secondary school students' attitudes toward chemistry reveals a neutral attitude  
4 regarding the interest and a negative attitude regarding the usefulness of the chemistry  
5 course to their future career. Only few students (about 4%) express the wish to study  
6 chemistry at University (Salta and Tzougraki, 2004). These neutral and negative  
7 attitudes are indices of a low motivation to study and learn chemistry (Koballa and  
8 Glynn, 2007). Taking into account the considerations noted above, we decided to  
9 investigate Greek secondary school students' motivation to learn chemistry using a  
10 translation and adaptation of SMQ II (Glynn *et al.*, 2011) in the domain of chemistry.  
11 This instrument was selected due to its psychometric features and wide usage.  
12 Particularly, SMQ II combines a number of key motivational components in a single  
13 scale consisted of five subscales, one for each construct, with strong experimental  
14 evidence for their validity (Glynn *et al.*, 2011). Questionnaire validity is an issue of  
15 central importance which is however seldom examined and/or established.

## 39 **Method**

### 40 *The context*

41  
42 The interpretation of the results of a motivational study is related to the context of the  
43 existing curriculum. Thus, in this section a short description of the Greek chemistry  
44 curriculum is given. Greek secondary school includes three years of lower (junior)  
45 and three years of upper (senior) secondary school. The curricula for secondary  
46 school are structured in six grades; 7<sup>th</sup>, 8<sup>th</sup>, 9<sup>th</sup> for lower and 10<sup>th</sup>, 11<sup>th</sup>, 12<sup>th</sup> for upper  
47 secondary school respectively. Secondary school science curricula are centralized. All  
48 schools throughout the country must follow a particular sequence of science courses  
49 and use the same educational materials authorized by the Ministry of Education.

The subject of chemistry is obligatory in grades 8 to 11 (core chemistry courses), and optional in the 12<sup>th</sup> grade (advanced chemistry course), depending on the direction of studies chosen by the student. At grades 8 and 9, the chemistry curriculum follows a

macroscopic to microscopic approach. This approach refers to instructional methods that use examples of real-world or demonstrations to introduce chemistry topics followed by microscopic explanations using two-dimensional drawings of dots and circles to represent atoms, ions, and molecules (Gabel, 1999). At grades 10 to 12, the chemistry curriculum, both in core and advanced courses, emphasizes a linear development of chemical concepts. This refers to instructional methods that start from subjects that introduce first basic theoretical concepts of atomic theory and bonding on the microscopic level and proceed to subjects focusing on the macroscopic level (Gabel, 1999). One of the chemistry curriculum objectives is the ability of students to solve algorithmic chemistry exercises and problems.

### *Participants*

The study was conducted in 4 urban public secondary schools located in the metropolitan area of the Greek capital, Athens. The participants were 330 secondary school students (163 males and 167 females) in grade 8 (n=146), and in grade 10 (n=184). The lower secondary school students (grade 8) were 14-15 years old and the upper secondary school students (grade 10) were 16-17 years old. Most students in the sample were of middle socioeconomic status. The students participated voluntarily without extra credit or compensation for their participation. The students and their parents were informed about the aim of this study.

### *Questionnaire Translation and Adaptation*

The Chemistry Motivation Questionnaire II (CMQ II) is the chemistry specific SMQ II version in which the word “chemistry” is substituted for the word “science”. SMQ II was selected for the following reasons: (a) it is based on a widely accepted

1  
2  
3 theoretical formulation of motivational constructs; (b) it functionalizes the  
4 motivational construct with a range of indicators, and (c) it demonstrates various  
5 psychometric properties which render it acceptable. The translation and adaptation  
6 process was conducted by taking into account the Hambleton comments on  
7 International Test Commission (ITC) guidelines for test translation and adaptation  
8 (Hambleton, 2001).  
9

10  
11  
12  
13  
14  
15  
16  
17  
18 A team of three translators working independently to translate and adapt the test was  
19 used. Scoring rubrics and instructions were also translated in the Greek language. The  
20 translators have knowledge of both languages. Knowledge of the cultures, and at least  
21 general knowledge of the subject matter and testing principles, made part of the  
22 selection criteria for translators. One of translators, the second author, is a science  
23 researcher who has lived for five years in USA during his doctoral studies, and he  
24 now lives and works in Greece. Consequently, he is familiar with the source and the  
25 target culture, and the concept of interest. The second translator is a science teacher  
26 with over twenty years experience in teaching science subjects at Greek secondary  
27 school and thus he is familiar with the culture of the population that will be studied.  
28  
29 Finally, the third translator is the first author, a chemistry educator, familiar both with  
30 the concept of interest and with literature on questionnaire development. A  
31 professional English language teacher (a native Greek with postgraduate studies in the  
32 UK) was also used as back translator.

41  
42  
43  
44  
45  
46  
47  
48  
49

50  
51 Prior to translation, the translators met to clarify the definitions and indicators of the  
52 concepts examined by the selected questionnaire in order to promote understanding of  
53 meanings and hence facilitate translation. Each team member first made an  
54 independent translation of the questionnaire. During forward translation, the  
55 translators focused on the meaning of the items rather than on literal word-for-word  
56  
57  
58  
59  
60

1  
2  
3 translation. After individual translations were made, the team members met in order to  
4  
5 review the translated version, discuss the discrepancies, and decide on the most  
6  
7 appropriate translation of the items. In the next phase, the back translation from the  
8  
9 target language into the source language was used in order to identify problems with  
10  
11 the forward translation. The team of translators then reviewed the back translation for  
12  
13 comparability of meaning with the target language and clarity of wording. Although  
14  
15 Hambleton (2001) states that a back translation provides little evidence of  
16  
17 measurement equivalence, in our case it was used to assure that the content and  
18  
19 meaning of the original items, instructions and response categories are the same as the  
20  
21 original. The last phase of the instrument preparation dealt with pre-testing the  
22  
23 translated questionnaire for comprehension and cultural validity. Five 10<sup>th</sup> grade  
24  
25 students completed the Greek version of CMQ II. The first author engaged the  
26  
27 students in a discussion to determine clarity of the items using questions such as  
28  
29 “What does the item mean?”, and “Was this an item you felt comfortable  
30  
31 responding?” The content of the discussion with the students was analyzed and a few  
32  
33 necessary changes were made to items by taking into account the students’  
34  
35 suggestions. In fact, a need of altering the wording of an item came to light. The  
36  
37 chemistry laboratory activities in Greek high school are considered complementary  
38  
39 without requiring both preparation of students and separate examinations or exam  
40  
41 questions. Consequently, the second part “...and labs” of item 16 “*I prepare well for*  
42  
43 *science tests and labs*” was considered not applicable for use in the Greek secondary  
44  
45 school context and it was deleted. This action does not create any problem in the  
46  
47 scoring procedure.

(<http://www.coe.uga.edu/assets/docs/outreach/smqii/SMQII-Translations.pdf>) in the form of Science Motivation Questionnaire II (Greek-SMQ II) applicable to all science disciplines. The team of translators attempted to find a balance between a literal and a culturally specific translation so that the translation and adaptation of items are appropriate for Greek secondary school students. Hence, the questionnaire in the target language was finalized and subjected to further testing of psychometric properties.

### *Procedure*

The questionnaire was administered to students in their chemistry classes by their chemistry teacher during March and April of school year 2012–2013. Students were informed about the study and they consented to participate. Their responses to all motivation statements were assessed using a Likert-type scale ranging from 0 (never) to 4 (always).

Confirmatory factor analysis (CFA) was selected as the procedure for statistical analysis since the present study aims to test the hypothesized motivational structure/model proposed by Glynn (2011) for students' motivation to learn chemistry. In contrast to Exploratory Factor Analysis (EFA) that may be appropriate for scale development, CFA is preferred when measurement models have strong hypothesis regarding the number of latent variables in a model (Usher and Pajares, 2009). Moreover, CFA provides a rigorous test of equivalence across the groups. If the assumption of equivalence is rejected, then EFA may be employed to discover where the anomalies are in the database (Hurley *et al.*, 1997).

The factors of the model correspond to the scales of related items identified by Glynn *et al.* (2011) that were hypothesized to represent the components of students'

1  
2  
3 motivation to learn chemistry. Adopting a componential model of motivation based  
4  
5 on the social cognitive theory, we hypothesized that (a) the students' responses to the  
6  
7 questionnaire can be predicted by the five specified components; (b) the components  
8  
9 are related because they measure positive, mutually supporting components of the  
10  
11 motivation. Confirmatory factor analysis was conducted using the Structural Equation  
12  
13 Modeling (SEM) software program AMOS, Version 21.  
14  
15  
16  
17  
18  
19  
20  
21

## 22 **Results**

### 23 *Model Specification*

24  
25 The five-factor model for the SMQ II proposed by Glynn and his colleagues (2011)  
26  
27 was validated for the chemistry domain and for Greek high school students. The  
28  
29 model included five latent (unobserved) variables (factors) : intrinsic motivation (IM),  
30  
31 self-determination (SD), self-efficacy (SE), career motivation (CM), and grade  
32  
33 motivation (GM). CFA was conducted in a manner that each latent variable (factor)  
34  
35 was "observed" via its specific set of five items (measured variable indicators).  
36  
37 Summarizing, the model to be confirmed contains 25 measured variables.  
38  
39 Specifically, the factor intrinsic motivation (IM) predicts the students' responses to  
40  
41 items 01, 03, 12, 17, and 19; the factor self-determination (SD) predicts the students'  
42  
43 responses to items 05, 06, 11, 16, and 22; the factor self-efficacy (SE) predicts the  
44  
45 students' responses to items 09, 14, 15, 18, and 21; the factor career motivation (CM)  
46  
47 predicts the students' responses to items 07, 10, 13, 23, and 25; and the factor grade  
48  
49 motivation (GM) predicts the students' responses to items 02, 04, 08, 20, and 24. It is  
50  
51 also necessary to confirm that the motivational factors may be intercorrelated.  
52  
53  
54  
55  
56  
57  
58  
59  
60 Therefore, the factors were permitted to covary. Error terms were hypothesized to be

1  
2  
3 uncorrelated. In each model the first item loading was constrained to 1.0 to set the  
4  
5 scale of measurement, and no items were allowed to double load.  
6  
7

### 8 9 10 *Model identification*

11  
12 A model is characterized as “identified” when “it is *theoretically* possible for the  
13  
14 computer to derive a unique estimate of every model parameter” (Kline, 2011). For  
15  
16 testing model identification, the first step is to count the number of data points and the  
17  
18 number of parameters that need to be estimated. The model to be confirmed has 265  
19  
20 fewer parameters than data points, so the model may be identified in accordance with  
21  
22 the required condition. Subsequently, the identifiability of the measurement portion of  
23  
24 the model is established by examining the number of factors and measured variables  
25  
26 as well as the error correlations and factor covariances (Kline, 2011). It is thus noted  
27  
28 that in the testing model, there are five indicators for each factor. The errors are  
29  
30 uncorrelated and each indicator loads on only one factor. In addition, the covariances  
31  
32 between the factors are not zero. Therefore, this CFA model may be identified (Kline,  
33  
34 2011).  
35  
36  
37  
38  
39  
40  
41  
42

### 43 *Model estimation*

44  
45 The model estimation starts with the evaluation of model fit which means the  
46  
47 determination of how well the model explains the data. Assuming satisfactory model  
48  
49 fit, the interpretation of the parameter estimates can take place (Kline, 2011). Multiple  
50  
51 well-established indices and criteria were used to assess the goodness of model fit,  
52  
53 because each given index evaluates only particular aspects of the model fit (Byrne,  
54  
55 2010; Kline, 2011). The analysis was conducted using maximum likelihood (ML)  
56  
57 estimation.  
58  
59  
60

1  
2  
3 The test of our hypothesis that the Chemistry Motivation Questionnaire (CMQ II)  
4 responses can be explained by five factors, yielded a  $\chi^2$  value of 569.31 with 265  
5 degrees of freedom and a probability of less than 0.001 ( $p < 0.001$ ), thereby suggesting  
6 that the fit of the data to the hypothesized model is not entirely adequate (Byrne  
7 2010). One of the chi squared test limitations, namely the sensitivity of  $\chi^2$  value to  
8 sample size, is a reason to consider that it may be a poor index of the quality of the fit  
9 when sample sizes are large (Hu *et al.*, 1992). The test of  $\chi^2/df$  ratio was proposed to  
10 address this problem (Byrne, 2010). The obtained value of 2.15 for the  $\chi^2/df$  ratio is  
11 considered a good fit of our hypothesized model to the data since it falls within the  
12 recommended range of 1.0 – 3.0 (Glynn *et al.*, 2011).  
13  
14  
15  
16  
17  
18  
19  
20  
21  
22  
23  
24  
25  
26

27 The following four additional fit indexes, which are among the most widely reported  
28 in the Structural Equation Modeling (SEM) literature, were also selected to determine  
29 model fit (Hu and Bentler, 1999; Kline, 2011): the Steiger–Lind Root Mean Square  
30 Error of Approximation (RMSEA), the Jöreskog–Sörbom Goodness of Fit Index  
31 (GFI), the Bentler Comparative Fix Index (CFI), and the Standardized Root Mean  
32 Square Residual (SRMR).  
33  
34  
35  
36  
37  
38  
39  
40

41 The first index, RMSEA, assesses a lack of fit of the population data to the estimated  
42 model and Hu and Bentler (1999) have suggested a value less than 0.06 as indicative  
43 of a good fit between the hypothesized model and the observed data. Moreover,  
44 MacCallum *et al.*, (1996) strongly urged the use of confidence interval in practice,  
45 suggesting a very narrow confidence interval as supporting for good precision of the  
46 RMSEA value in reflecting a model fit in the population. The RMSEA value for our  
47 hypothesized model is 0.06, with the 90% confidence interval ranging from 0.05 to  
48 0.07. This indicates that we can be 90% confident that the true RMSEA value in the

population will fall within the bounds of 0.05 and 0.07, which represents a good degree of precision (Byrne, 2010).

The second index, GFI, is an alternative to the Chi-Square test and calculates a weighted proportion of variance in the sample covariance accounted for by the estimated population covariance matrix (Tabachnick and Fidell, 2000). A GFI value of 0.90 or higher indicates a good model fit. Although the GFI value for our hypothesized model (0.88) is slightly lower than the threshold level, it is generally perceived as “acceptable” for other indices of fit (Byrne, 2010).

The third index, CFI, takes into account sample size (Byrne, 2010) and performs well even in small samples (Tabachnick and Fidell, 2000). A value greater than 0.90 is needed in order to ensure that models are accepted, with values close to 0.95 indicating superior fit (Hu and Bentler, 1999). The CFI value for our hypothesized model (0.91) is indicative of good fit.

The last index, SRMR, is a measure of the mean absolute correlation residual, the overall difference between the observed and predicted correlations. Small values of SRMR (less than 0.05) indicate good-fitting models (Byrne, 2010), however values as high as 0.08 are deemed acceptable (Hu and Bentler, 1999). The SRMR value of our hypothesized model, equal to 0.06, can be interpreted as meaning that the model explains the correlations to within an average error of 0.06 (Byrne, 2010). As mentioned above, the model chi-square is statistically significant, so the exact-fit hypothesis is rejected; however the values of the other four used fit indices indicate that our hypothesized model fits the data well, providing evidence of questionnaire construct validity.

To examine measurement invariance across different groups, successive multi-group CFAs were conducted (Vandenberg and Lance, 2000). Factorial invariance tests were

1  
2  
3 done in hierarchical fashion by conducting initially the most basic form of  
4 measurement invariance that is configural invariance or equal form invariance (Model  
5  
6 1). If configural invariance is confirmed, this indicates that participants belonging to  
7  
8 different groups conceptualize the constructs in the same way. A stronger form of  
9  
10 measurement invariance is construct-level metric invariance or equal factor loadings  
11  
12 (Model 2), which means that the unstandardized factor loadings of each indicator are  
13  
14 equal across the groups. Metric invariance is important as a prerequisite for  
15  
16 meaningful cross-group comparison (Cheung and Rensvold, 2002). When metric  
17  
18 invariance is met, the suggestion is that different groups respond to the items in the  
19  
20 same way. Subsequently, constraints to factor loadings and item intercepts are  
21  
22 imposed in order to test for scalar or strong invariance (Model 3). Establishing scalar  
23  
24 invariance indicates that individuals who have the same score on the latent construct  
25  
26 would obtain the same score on the observed variable regardless of their group  
27  
28 membership. A value of  $\Delta CFI$  smaller than or equal to 0.01 indicates that the null  
29  
30 hypothesis of invariance should not be rejected (Cheung and Rensvold, 2002) and it is  
31  
32 indicative of model invariance.  
33

34  
35 Recall that CFAs were conducted on increasingly-restrictive hierarchical  
36  
37 measurement models for each of the two subgroups of interest: gender and age. To  
38  
39 assess how well the CFA models represented the data, the following criteria were  
40  
41 used as cut-offs for good fit: CFI >0.90 (with >0.95 being ideal), RMSEA and SRMR  
42  
43 <0.08 (with <0.05 being ideal) (Hu and Bentler, 1999). Because the measurement  
44  
45 model showed a modestly good fit for all four subgroups namely girls, boys, lower,  
46  
47 and upper secondary school students, (Table 3), we specified the same model for each  
48  
49 subgroup when testing for factorial invariance.

**Table 3:** Summary of Goodness-of-Fit Statistics for the Chemistry Motivation Questionnaire II Measurement Model by Subgroup

SubgroupModel	$\chi^2$	df	$\chi^2/df$	CFI	RMSEA	SRMR
Girls	499.43	265	1.89	.86	.07 (.06-.08)	.07
Boys	444.16	265	1.68	.90	.06 (.05-.07)	.07
Lower Secondary	456.79	265	1.72	.84	.07 (.06-.08)	.07
Upper Secondary	474.00	265	1.79	.91	.07 (.06-.08)	.07
Total	569.31	265	2.15	.91	.06 (.05-.07)	.06

Multiple groups modeling started with testing for configural invariance. As Table 4 shows, the model gave a modestly good fit with the data supporting the configural validity across gender and different age groups. With regard to metric invariance, the results revealed that the model fits the data very well across gender and different age groups.

**Table 4:** Tests for Invariance of the Chemistry Motivation Questionnaire II Measurement Model across Gender and Age

Model	$\chi^2$	df	$\chi^2/df$	CFI	RMSEA (90% CI)	Model comparison	$\Delta CFI$
<b>Boys vs Girls</b>							
Model 1 (no constrains)	943.588	530	1.780	.88	.049 (.044-.054)		
Model 2 (equal factor loadings)	959.826	550	1.745	.88	.048 (.043-.053)	2vs1	.000
Model 3 (equal intercepts)	976.345	565	1.728	.88	.047 (.042-.052)	3vs2	.000
<b>Lower vs Upper Secondary</b>							
Model 1 (no constrains)	930.788	530	1.756	.89	.048 (.043-.053)		
Model 2 (equal factor loadings)	952.122	550	1.731	.89	.047 (.042-.052)	2vs1	.000
Model 3 (equal intercepts)	972.279	565	1.721	.89	.047 (.042-.052)	3vs2	.000

Furthermore, this additional set of constraints did not lead to a meaningful drop in fit ( $\Delta CFI = 0.000$ ) between Model 2 and Model 1, providing support for metric invariance across gender and age groups. Subsequently, scalar invariance was investigated. The overall goodness-of-fit indices and  $\Delta CFI$  value between Model 3 and Model 2 across gender and age groups supported scalar invariance. Although the CFI values for all CFA models are slightly lower than the threshold level, they are

generally perceived as “acceptable” for other indices of fit. Statisticians (Byrne, 2010) frequently point out that fit indexes can only describe a model’s “lack of fit” (p. 84) and that the judgment of a model’s adequacy “rests squarely on the shoulders of the researcher”. With this in mind and based on the majority of the evaluated indexes, we have strong evidence that: (a) participants belonging to different groups conceptualize the constructs in the same way (configural invariance); (b) different groups respond to the items in the same way (metric invariance); (c) individuals who have the same score on the latent construct would obtain the same score on the observed variable regardless of their group membership (scalar invariance). Thus, cross-group comparisons are plausible as well.

Table 5 lists each item in the Chemistry Motivation Questionnaire II along with its standardized loading estimate for each of the five measurement factors.

**Table 5:** Standardized Factor Loadings

CMQ II Item Number	Factor Loading					Statement
	Total	Boys	Girls	Lower Secondary	Upper Secondary	
<b>Factor:Grade motivation</b>						
24	.78	.79	.79	.76	.77	Scoring high on chemistry tests and labs matters to me
4	.76	.69	.84	.68	.80	Getting a good chemistry grade is important to me
8	.75	.78	.71	.79	.72	It is important that I get an “A” in chemistry
20	.67	.66	.70	.58	.71	I think about the grade I will get in chemistry
2	.57	.52	.60	.53	.60	I like to do better than other students on chemistry tests
<b>Factor:Self- efficacy</b>						
15	.80	.82	.78	.75	.84	I believe I can master chemistry knowledge and skills
9	.79	.77	.81	.72	.83	I am confident I will do well on chemistry tests
18	.70	.77	.60	.66	.73	I believe I can earn a grade of “A” in chemistry
14	.64	.60	.70	.61	.66	I am confident I will do well on chemistry labs and projects
21	.56	.62	.51	.49	.62	I am sure I can understand chemistry
<b>Factor:Self-determination</b>						
22	.74	.75	.72	.69	.78	I study hard to learn chemistry
11	.70	.70	.69	.70	.71	I spend a lot of time learning chemistry
16	.60	.60	.60	.66	.56	I prepare well for chemistry tests
5	.60	.63	.52	.50	.66	I put enough effort into learning chemistry

CMQ II Item Number	Factor Loading					Statement
	Total	Boys	Girls	Lower Secondary	Upper Secondary	
6	.56	.58	.49	.52	.59	I use strategies to learn chemistry well
<b>Factor: Career motivation</b>						
13	.78	.79	.75	.66	.86	Understanding chemistry will benefit me in my career
23	.78	.79	.76	.79	.80	My career will involve chemistry
25	.73	.73	.75	.73	.77	I will use chemistry problem-solving skills in my career
7	.72	.67	.72	.50	.83	Learning chemistry will help me get a good job
10	.69	.66	.76	.58	.74	Knowing chemistry will give me a career advantage
<b>Factor: Intrinsic motivation</b>						
19	.80	.78	.81	.75	.84	I enjoy learning chemistry
12	.71	.69	.72	.67	.74	Learning chemistry makes my life more meaningful
17	.67	.71	.61	.58	.73	I am curious about discoveries in chemistry
3	.66	.65	.65	.55	.75	Learning chemistry is interesting
1	.48	.55	.36	<b>.34</b>	.59	The chemistry I learn is relevant to my life

The factor loadings are estimated correlations often referred to as validity coefficients, which indicate how well a given item measures its corresponding factor. In all analyses, the standardized factor loadings were significant at the  $p=0.05$  level and all, except one which is equal to 0.34 for the lower secondary group (shown in bold), displayed magnitude in the range between 0.86 and 0.48, and therefore exceed the factor-loading criterion of 0.35 (Tabachnick and Fidell, 2000).

The standardized correlations among the factors shown in Table 6 are considered corrected (i.e., disattenuated) for measurement error and thus may be viewed as representing the true associations among the motivation components represented by the factors.

**Table 6:** Standardized Factor Correlations for all groups

	Grade motivation					Self-efficacy					Self-determination					Career motivation					
	T*	B*	G*	L*	U*	T*	B*	G*	L*	U*	T*	B*	G*	L*	U*	T*	B*	G*	L*	U*	
<b>GM</b>																					

	Grade motivation					Self-efficacy					Self-determination					Career motivation				
<b>SE</b>	.66	.65	.65	.59	.77															
<b>SD</b>	.56	.60	.53	.52	.60	.45	.51	.41	.40	.49										
<b>CM</b>	.48	.53	.40	.40	.52	.54	.66	.41	.48	.58	.37	.47	<b>.23</b>	.46	.32					
<b>IM</b>	.48	.47	.49	.44	.53	.57	.58	.59	.57	.58	.53	.56	.46	.53	.53	.70	.69	.69	.72	.67

**Note:** Minimum and maximum values are shown in bold

\* T: Total, B: Boys, G: Girls, L: Lower secondary, U: Upper Secondary

The five factors showed statistically significant intercorrelations ranging in magnitude from 0.23 (between career motivation and self-determination for girls) to 0.77 (between grade motivation and self-efficacy for upper secondary students).

A thorough psychometric evaluation also includes some form of reliability evidence.

The reliabilities (internal consistencies) of the subscales for the all groups, assessed by Cronbach's alphas, are presented in Table 7.

**Table 7:** Reliability of internal consistencies

	Reliability of internal consistencies				
	Total (n=330)	Boys (n=163)	Girls (n=167)	Lower secondary (n=146)	Upper secondary (n=184)
<b>GM</b>	.82	.81	.84	.79	.83
<b>SE</b>	.82	.84	.80	.78	.85
<b>SD</b>	.77	.78	.73	.75	.79
<b>CM</b>	.86	.85	.86	.79	.90
<b>IM</b>	.80	.81	.76	.71	.85
<b>All items</b>	.91	.92	.90	.88	.93

The values of Cronbach's alpha of the five factors ranged in magnitude from 0.71 (intrinsic motivation for lower secondary school students) to 0.90 (career motivation for upper secondary school students). According to DeVellis (2003), a coefficient

1  
2  
3 above 0.80 is “very good,” 0.70 to 0.80 is “respectable,” 0.60 to 0.69 is  
4  
5 “undesirable to minimally acceptable,” and below 0.60 is “unacceptable.” The  
6  
7 Cronbach’s alpha values of all 25 items ranged from 0.88 (lower secondary school  
8  
9 students) to 0.93 (upper secondary school students). Analogous values of coefficients  
10  
11 were reported by Glynn *et al.* (2011) for the scales of SMQ II.  
12  
13

14  
15 Boys and girls as well lower and upper secondary school students were compared on  
16  
17 their motivation components using the mean factor-based scale scores (Table 8). We  
18  
19 adopted the factor-based scale scores instead of the estimated factor scores because  
20  
21 the former are more easily interpreted and can also be used for comparison between  
22  
23 studies (Glynn *et al.*, 2011). A two-way ANOVA was conducted to determine  
24  
25 possible differences in students' mean scores on the scales of CMQ II according to  
26  
27 age (lower secondary school and upper secondary school), gender (boys and girls),  
28  
29 and the interaction of these variables.  
30  
31  
32

33  
34 The ANOVA results revealed a significant main effect of students' age on their grade  
35  
36 motivation scores,  $F(1, 326)=9.242, p<0.05$ . Moreover, there were significant main  
37  
38 effects of students' gender on their self-determination scores,  $F(1, 326)= 13.108,$   
39  
40  $p<0.001$ , their career motivation scores,  $F(1, 326)= 6.209, p<0.05$ , and the intrinsic  
41  
42 motivation scores,  $F(1, 326)= 15.077, p<0.001$ . Nevertheless, no significant  
43  
44 interactions ( $p > 0.05$ ) were observed between age and gender for any of the students'  
45  
46 scores on the scales of CMQ II. This actually means that the effect of the students'  
47  
48 age on their grade motivation scores is fairly similar for male and female students. The  
49  
50 effect of gender on self-determination, career motivation, and intrinsic motivation  
51  
52 scores is also similar for lower and upper secondary students.  
53  
54  
55  
56

57  
58 **Table 8:** Descriptive statistics of CMQ II scales among boys and girls students in  
59  
60 lower and upper secondary school.

	Lower secondary				Upper Secondary		
	Boys (n=67)	Girls (n=79)	Total (n=146)		Boys (n=96)	Girls (n=88)	Total (n=184)
<b>Grade motivation (min=0, max=20)</b>							
M	14.69	15.32	<b>15.03</b>		13.34	13.73	<b>13.53</b>
sd	4.01	4.06	<b>4.03</b>		4.81	4.30	<b>4.56</b>
<b>Self-efficacy (min=0, max=20)</b>							
M	11.90	11.71	11.80		12.81	12.53	12.68
sd	4.42	3.44	3.91		4.21	3.86	4.04
<b>Self-determination (min=0, max=20)</b>							
M	<b>9.87</b>	<b>11.30</b>	10.64		<b>9.66</b>	<b>11.28</b>	10.43
sd	<b>4.09</b>	<b>3.69</b>	3.93		<b>4.02</b>	<b>3.45</b>	3.84
<b>Career motivation (min=0, max=20)</b>							
M	<b>8.33</b>	<b>10.15</b>	9.32		8.76	9.65	9.19
sd	<b>4.53</b>	<b>4.21</b>	4.44		5.15	5.42	5.29
<b>Intrinsic motivation (min=1, max=20)</b>							
M	<b>11.08</b>	<b>13.30</b>	12.28		11.53	12.73	12.10
sd	<b>3.92</b>	<b>3.37</b>	3.79		4.44	3.96	4.25

**Note:** The results of the factors that showed statistically significant differences are shown in bold

The mean factor-based scale scores are shown in Table 8. Examination of the means in Table 8 and the results of ANOVA show that lower secondary school students have significantly higher scores on grade motivation than students in upper secondary school. In regard with gender, statistical analysis indicates the following: a) Girls in lower secondary school have significantly higher scores on self-determination, career motivation and intrinsic motivation relative to boys of the same age, b) Girls in upper secondary school have statistically significant higher score in self-determination relative to boys of the same age.

## Discussion

Validity and reliability of quantitative measurements are the two most important aspects of educational research. Although the use of existing instruments is convenient, these instruments should not be used without sufficient evidence of their ability to produce valid and reliable scores in the desired context. Only if the instruments' scores are valid and reliable they can result to valid interpretations, and can lead to potentially gainful decisions for students as well as for educational researchers and policy makers. Consequently, access to valid instruments is crucial for researchers conducting quantitative research in chemistry education.

Thus the first main contribution of this work is the provision of solid experimental evidence for the validity and reliability of the SMQ II instrument, originally developed for measuring motivation among college students in USA (Glynn *et al.*, 2011), in a specific science subject (Chemistry) a different cultural context (Greece) and in students belonging to a younger age group (14-17 y) and a different educational level (secondary school). This opens the possibility for reliable measurement of students' motivation within the Greek cultural context for the first time and in addition for reliable cross-cultural comparisons of students' motivation via the use of the same valid instrument. The second main contribution of this work is the investigation of Greek secondary school students' motivation to learn chemistry for the first time.

Confirmatory Factor Analysis (CFA) was used to test the hypothesized motivational structure proposed by Glynn *et al.*(2011) for students' motivation to learn chemistry, for the Greek version of the chemistry-specific original questionnaire (Greek-CMQ II). It is important to note that CFA was employed not only in order to verify whether the original factor structure could be validated, but also in order to examine whether

1  
2  
3 the measurement structure underlying motivation to learn chemistry is equivalent  
4 within the (sub)groups corresponding to gender and age. In previous studies,  
5 comparisons between group means were made based on the assumption that the  
6 measures of motivation are fully applicable within the specific groups as well. In our  
7 study, we first used multi-group CFA in order to confirm that the measures are  
8 invariant within groups and subsequently conducted comparisons between these  
9 groups (Byrne, 2010; Kline, 2011). The results of statistical analyses provided  
10 evidence supporting the construct validity of Greek CMQ-II, as well as for configural,  
11 metric and scalar invariance, thus allowing meaningful comparisons between groups.  
12 Thus the five component model of motivation consisting of grade motivation, career  
13 motivation, intrinsic motivation, self-efficacy, and self-determination was also  
14 confirmed for the Greek version of CMQ-II. The scales were positively related,  
15 consistent with the view that the components were mutually supporting. In particular,  
16 intrinsic motivation and career motivation were strongly related, suggesting that  
17 intrinsic motivation orientates students to careers that involve chemistry. Self-efficacy  
18 and grade motivation were also strongly related, supporting that self-efficacy predicts  
19 students' performance, in line with previous studies' findings (Britner, 2008; Schraw  
20 *et al.*, 2005; Taasobshirazi and Glynn, 2009; Zusho *et al.*, 2003). Although most  
21 correlations between scales of CMQ II are similar with those of SMQ II (Glynn *et al.*,  
22 2011), the correlations between self-efficacy and grade motivation, as well as between  
23 intrinsic motivation and grade motivation are higher. This finding might be  
24 interpreted by the main idea of self-determination theory that there is not a clear  
25 distinction between intrinsic and extrinsic types of motivation but motivated  
26 behaviours vary in the degree to which they are autonomous (intrinsically motivated)  
27 vs. controlled (career or grade motivated) (Ryan and Deci, 2000). The reliabilities

2  
3 (internal consistencies) of the scales of the Greek version of CMQ II for all four  
4 subgroups namely girls, boys, lower, and upper secondary school students, assessed  
5 by Cronbach's alpha values, were analogous of those reported by Glynn *et al.* (2011)  
6 for the scales of SMQ II. Particularly, the reliabilities of the scales for upper  
7 secondary school students are very similar to those reported by Glynn *et al.* (2011) for  
8 college students, suggesting the very good fitness of the scales for these ages.  
9

10  
11 Our findings suggest that the structure of CMQ II (number of factors and factor-item  
12 association) is not dependent on gender and age group. In addition, both genders and  
13 age groups have equal strengths of relations between the underlying constructs and  
14 specific scale items.  
15

16  
17 Furthermore, our findings revealed interesting statistically significant differences  
18 between specific means of the CMQ II scales across the genders and the examined  
19 age groups. More specifically, lower secondary students had higher mean score on  
20 grade motivation than upper secondary students. In the other four scales, there is no  
21 evidence for statistically significant differences between the two age groups. Previous  
22 research findings support that most students show a progressive deterioration on  
23 school-related attitudes and motivation (Gentry *et al.*, 2002; Gottfried *et al.*, 2001;  
24 Wigfield and Eccles, 2002). Our work provides similar evidence only for the  
25 motivation component related with grade motivation. Although the decline in  
26 students' motivation to learn science has been documented and is evidenced by many  
27 science teachers, studies have shown that this decline is not an attribute of  
28 adolescence, but a result of school and class context (Nolen, 2003; Vedder-Weiss and  
29 Fortus, 2011). A limitation of the present study is the fact that it is based on a cross-  
30 sectional research design. Cross-sectional samples do not accurately capture true  
31 intra-person change and preclude assessment of measurement invariance over time  
32

59  
60

1  
2  
3 and as people age. A longitudinal research design is required in order to address these  
4  
5 concerns.  
6

7  
8 In regard with differences between genders, secondary school female students  
9  
10 exhibited higher means than male on self-determination irrespective of age group.  
11  
12 Furthermore, the female students of the younger age group (lower secondary school)  
13  
14 had higher means than corresponding male students on two additional motivational  
15  
16 components: career motivation and intrinsic motivation. No significant inter-gender  
17  
18 differences were found for the grade motivation and self-efficacy component scales.  
19  
20 The results related with the difference between boys and girls in self-determination  
21  
22 are in line with findings from previous studies (e.g. Cavallo *et al.*, 2004; Glynn *et al.*,  
23  
24 2009; 2011). However, our findings contradict those of Glynn *et al.* (2011) which  
25  
26 indicated that men had higher self-efficacy than women, but are in line with those of  
27  
28 Britner (2008) which indicate no gender differences in self-efficacy in physical  
29  
30 science. Concentrating on the comparison of this work with the results of Glynn *et al.*  
31  
32 (2011), since in both cases measurements were made via the use of equivalent  
33  
34 instruments (SMQ II and Greek CMQ II), the documented differences concerning the  
35  
36 inter-gender comparison of motivation could be attributed to several factors (acting  
37  
38 separately or synergistically) such as: a) different age of students, b) different cultural  
39  
40 context, c) different educational context, d) investigation of a specific science domain  
41  
42 (chemistry) in our case. Research on gender differences in motivation to learn science  
43  
44 and mathematics (Li, 1999; Tenenbaum and Leaper, 2003) points out that such  
45  
46 differences are attributed to social influences (eg family, teachers, friends, media)  
47  
48 rather than to natural differences between boys and girls. Such a social influence that  
49  
50 could possibly justify the herein documented increased motivation of female lower  
51  
52 and/or upper secondary school students relative to their male classmates with regard  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 to self-determination, career motivation and intrinsic motivation, is the increased ratio  
5  
6 of female vs male chemistry teachers in Greek secondary education. The large  
7  
8 presence of female chemistry teachers in Greek secondary schools serves as a positive  
9  
10 role model for the female students.  
11

12  
13 Elaborating more on the comparison of the total scores of our results with those of  
14  
15 Glynn *et al.* (2011), the following main comments can be made:  
16

17  
18 i) An interesting finding of our work is related with the especially low mean factor-  
19  
20 based scores of the career motivation scale. As seen in Table 8, the absolute values of  
21  
22 these scores are the lowest relative to the other four motivation components and  
23  
24 below 10 (in a scale from 0 – 20) for the whole sample (equal to 9.39/20 and 9.19/20  
25  
26 in the two age groups). These scores are much lower relative to the one of science  
27  
28 majors in USA (that is equal to 15.95/20) which is not a surprising finding since the  
29  
30 sample of the latter case involves older students who already pursue studies related  
31  
32 with a career in science. However, the career motivation scores of the Greek students  
33  
34 are also significantly lower relative to the corresponding score of the non-science  
35  
36 majors in USA (equal to 11.13). Thus, the present study provides a direct  
37  
38 measurement of the poor motivation of Greek students to pursue a chemistry related  
39  
40 career, a fact which was inferred in the study of Salta *et al.* (2012).  
41  
42  
43  
44

45  
46 ii) With regard to self-determination, the cross-cultural comparison reveals a very  
47  
48 similar pattern with the one discussed above for career motivation. In fact, Greek  
49  
50 secondary school students have a quite low mean absolute score in self-determination  
51  
52 (10.64/20 and 10.43/20 in the two age groups) which is much lower from the  
53  
54 corresponding scores of college students in USA (equal to 15.20/20 and 13.61/20 for  
55  
56 science and non-science majors respectively). This large documented difference in  
57  
58 self-determination between the two countries could be partly related with the different  
59  
60

1  
2  
3 educational context of the examined student samples. A college learning environment  
4 is often more flexibly structured relative to secondary school. However, the especially  
5 low self-determination scores of Greek secondary school students could also be linked  
6 to certain features of the Greek chemistry curriculum. In fact, as recently pointed out  
7 by Greek researchers in science education (Halkia and Mantzouridis, 2005), the  
8 demanding content of the Greek chemistry curriculum poses major difficulties to the  
9 teachers since it leaves them very little freedom to use other teaching resources apart  
10 from the provided science textbook. This chemistry curriculum has to be covered in a  
11 small number of teaching hours (1 or 2 per week depending on grade, see Table 1). In  
12 addition, the possibility for hands-on experimentation is also very limited (2-4 one-  
13 hour lab experiments per year depending on grade, see Table 2). These structural  
14 characteristics of the Greek educational system are expected to have a detrimental  
15 effect on Greek secondary school students' sense of control over their learning  
16 chemistry (self-determination) as well as in the other components of motivation to  
17 learn chemistry.

38  
39 iii) The total mean scores of grade motivation of college students in USA (equal to  
40 16.96/20 and 16.11/20 for science and non-science) are much higher relative to the  
41 one of upper secondary school Greek students (equal to 13.53/20) and increased also  
42 relative to the one of Greek lower secondary school students (equal to 15.03/20). This  
43 difference could be most closely related to the different educational context of the two  
44 student samples. College students (irrespective of major) have already made a  
45 conscious choice of pursuing higher level studies for getting a tertiary degree while  
46 high school students are not in a position to make specific choices over the courses  
47 they have to study for getting their secondary education certificate.

iv) With regard to the remaining two motivation components, self-efficacy and intrinsic motivation, the mean scores displayed by the Greek secondary school students are decreased relative to college science majors but quite similar in magnitude with non-science majors in USA. The increased values for science majors are not surprising taking into account the fact that these are students who have already chosen a study path related to science. On the other hand, the display of similar self-efficacy and intrinsic motivational characteristics between students who have consciously chosen a non-science major (USA) and secondary education students (Greece) may be, among others, related to perceptions most students tend to have about the nature of the chemistry course irrespective of country of origin.

Research studies that provide novel empirical and/or theoretical content on a science education topic in a novel educational context are expected to provide significant contributions to scientific knowledge (Taber, 2012). The availability of a valid tool, such as the Greek version of Chemistry Motivation Questionnaire II, for exploring quantitatively the motivation of Greek secondary school students to learn chemistry opens several new possibilities for researchers, chemistry educators as well as educational policy makers in Greece. Its application to carefully selected student samples could provide valuable information and feedback which can be employed for increasing the effectiveness of chemistry curricula, teaching materials and teaching methodologies. Future research should be focused on identifying the elements of school culture and teacher practices which have the strongest influence on students' motivation for chemistry learning as well as their in-between interactions.
