DOI: 10.1039/b000000x

Reactions promoted by stoichiometric amounts of silver salts suffer from high cost, limited availability and raise environmental concerns. This manuscript describes studies leading to the discovery of a general replacement for silver with an inexpensive and convenient organic salt in palladium catalysed direct C(sp²)–H and C(sp³)–H arylation reactions.

One of the fundamental goals in chemical research is the development of broadly applicable, cost-effective, practical and sustainable synthetic methods. In this context, the development of C–H bond arylation processes has attracted significant interest as more environmentally-friendly alternatives to traditional cross-couplings. These new transformations use readily available starting materials, thus avoiding the preparation and use of organometallic reagents as coupling partners and the associated generation of stoichiometric amounts of metallic waste.

In 2005, Daugulis and Zaitsev developed a method for the direct arylation of anilides with iodoarenes using a catalytic system involving Pd(OAc)₂ in combination with stoichiometric AgOAc. This powerful system and its various modifications have since been successfully applied to a great variety of C–H arylation processes involving iodoarene coupling partners (Scheme 1). However, to date one of the major drawbacks of these methodologies is the requirement for stoichiometric silver additives. Silver(I) salts are a uniquely appropriate partner for Pd, Au, Cu, Rh, Ru and Pt catalysts, particularly when halide abstraction is required in the catalytic process. However, due to the ability of silver salts to also act as oxidants and Lewis acids, sometimes undesired side reactions are observed. Furthermore, when used as stoichiometric reagents, these expensive silver salts considerably increase the overall cost of the process and generate significant amounts of metal waste. Therefore those transformations are prohibitively expensive for industry. Importantly, whereas there are alternatives to Ag salts in their role of oxidants, the only other well-known halide scavengers (Pb, Ti and Hg salts) are highly toxic and rarely used for this purpose.

Recent studies on the use of Ag salts as additives in Au-catalyzed reactions have shown that, in addition to abstracting a halogen, Ag may play additional roles essential to the catalytic process and form mixed Au–Ag active species. In the case of C–H arylation reactions, it is possible that Ag salts may also be acting as terminal oxidants, assisting in the oxidative addition step or facilitating the C–H activation. A recent mechanistic study on the role of additives in palladium acetate-catalyzed ortho-C–H bond functionalizations suggested that Ag interacts with Pd in a cooperative manner for an enhanced heterobimetallic C–H activation. We now report studies that demonstrate that the role of silver salts in several C–H arylation processes with iodoarenes is exclusively that of iodide capture. Furthermore, we have identified that in these processes silver salts can be conveniently replaced with a more redox stable and inexpensive quaternary ammonium salt while maintaining the high reactivity and broad substrate class scope displayed by the previous Pd/Ag systems.

To the best of our knowledge, this is the first example of a silver replacement of general applicability to a wide range of C–H arylation processes.

Scheme 1 Selected Examples of the General Scope of Current Protocols for C–H Arylation Using Iodoarenes and Stoichiometric Silver Salts.

Our initial efforts were directed at assessing the role of Ag salts in a common C–H arylation methodology: the ortho-arylation of benzoic acid 1a with iodoarene 2a (Table 1). Reaction under standard, Ag salt-mediated, conditions led to formation of biaryl product 3aa in 87% yield (entry 1).

Replacement of AgOAc with KOAc led to a reduction in yield to 9%, quite consistently with two turnovers of the Pd catalyst (entry 2). A qualitative colorimetric test suggested the presence of PdI₂ in the reaction mixture.⁹ Replacing Pd(OAc)₂ with PdI₂ led to no reaction (entry 3). Finally, using PdI₂ in combination with AgOAc fully restored the high reactivity of the system (entry 4). These results suggest that in these reactions Pd(OAc)₂ is a competent catalyst for the C–H arylation process, but is poisoned by iodide after two turnovers (Scheme 2). Thus, the silver salt is required for regenerating catalytically active Pd(OAc)₂ from inactive PdI₂ via the formation and precipitation of the highly insoluble AgI salts, and not for the C–H arylation itself.

Reactions were carried out using 0.5 mmol of 1a and 3 equiv of 2a. Yields were determined by ¹H NMR analysis using an internal standard.

Scheme 2 Poisoning and Regeneration of Pd Catalyst in C–H Arylation.

Having established that Ag salts are not intrinsically required for the C–H arylation process, we hypothesised that a more benign acetate salt could equally facilitate regeneration of the Pd catalyst if the acetate counter-cation produced a highly insoluble iodide salt within the reaction medium. To examine the validity of this hypothesis, we investigated the replacement of AgOAc with a variety of acetate salts (Table 2). The addition of NaOAc, CsOAc or Cu(OAc)₂ proved to be ineffective for the regeneration of the catalyst (entries 1-3).¹¹ To our delight, a survey of quaternary ammonium salts (entries 4-7) revealed that tetramethylammonium acetate could be used to regenerate the catalyst (entry 5), leading to the product in 45% yield (ca 9 catalyst turnovers). Further, NMe₄OAc could be formed in situ by the equimolar combination of the more readily available and inexpensive NMe₄Cl and KOAc (entry 8). An experiment using unreactive PdI₂ demonstrated that, like AgOAc, NMe₄OAc salts are able to regenerate catalytically active Pd species in situ (entry 9). Increasing the equivalents of base and iodide abstractor gave an improved yield (entries 10 and 11), with 2.05 equiv of NMe₄Cl affording similar yields of product to those obtained using AgOAc (compare entry 11 with entry 1 in Table 1).¹²

Unless otherwise noted, all reactions were carried out using 0.5 mmol of 1a and 3 equiv of 2a. Yields were determined by ¹H NMR analysis using 1,3,5-trimethoxybenzene as an internal standard. Reaction run for 48 h. NMe₄Cl and KOAc added in two portions.

The effect of NMe₄ salts on the catalytic activity is remarkable, in particular when compared with the ineffective ammonium salts bearing much larger (NBu₄ and NEt₄) or smaller (NH₄) cations. This may be due to a more favourable cation/anion radii ratio, leading to a more effective crystal packing of the corresponding iodide salt.¹³ The solubility of NMe₄I in AcOH was determined to be lower than 0.3 mg per mL, which compares favourably to the higher solubilities of NH₄I (4.7 mg per mL), NEt₃I (6.5 mg per mL) and NBu₄I (647 mg per mL).

Having found a suitable cheap and benign replacement for Ag(I) salts, we explored the effects of substitution in both the benzoic acid and the iodoarene coupling partners (Scheme 3). Gratifyingly, both electron-poor and electron-rich iodoarenes led to the corresponding biaryl products in yields similar to, or higher than, those reported for the same AgOAc mediated process (3ab-3ae).¹⁴c Varied substitution was also possible on the benzoic acid and para substituted benzoic acids (3ha-3ha).
We envisaged that formation of unreactive PdI₂ may be a common intermediate in the majority of Pd(II)-catalysed C–H arylation reactions with iodoarene coupling partners. Therefore, we explored the general applicability of NMe₄OAc as an organic analogue for Ag(I)-salts to a wide variety of C–H arylation reactions (Scheme 4). It is noteworthy that simply by adjusting a few reaction parameters the system could be applied to other classes of substrates. Using free amides instead of carboxylic acids as the directing group, the NMe₄-mediated protocol furnished the biaryl products in good yield (3ia–3jd). Other common directing groups for C–H arylation, pyridine and benzoquinoline, were also successfully used under silver-free conditions (3kg–3lg). We then explored the application of our arylation protocol to other heteroarenes in the absence of a directing group. Remarkably, this protocol also allowed the arylation of N-methylindole and 2-chlorothiophene in good yields (3ma–3ng).

The development of NMe₄-promoted reactions offers major economical and practical advantages over existing Ag-mediated methods. Firstly, the method provides a new avenue to reduce the cost of a number of chemical processes; NMe₄Cl is ca. 50 times cheaper than AgOAc,¹⁴ and is produced in large scale (>5,000 tons/year). Secondy, the synthetic advancement is also favourable from an environmental point of view; while AgOAc and AgI are both classed as very toxic to the aquatic environment, NMe₄OAc and its by-product NMe₄I¹⁵ are only classed as irritants. Moreover, the tolerance of the system covers a broad range of chemical motifs and the procedure is operationally trivial; the reaction proceeds smoothly under air with no special precautions needed. Overall, the methodology greatly increases the potential for C–H bond direct arylations to be exploited in pharmaceutical and agrochemical industries, where the value of a
synthetic process is mainly assessed by the viability in terms of cost and environmental impact.

\[
\text{Scheme 6 Scale-up of the silver-free arylation reaction. See ESI for full details.}^\dagger
\]

In order to demonstrate the utility of the new silver-free coupling for process chemistry, we scaled up the reaction more than 3,000 times in a 5 L reactor. Further optimization of the method allowed the arylation of 1.6 mol (218 g) of \( \text{C}(\text{sp})^2 \) iodobenzene (2b) and 2 mol % \( \text{Pd(OAc)}_2 \) (Scheme 6). After an acid-base work-up, the reaction afforded 295 g of product 3b in 87% yield with a 97% a/a purity by HPLC suitable for most applications. The purity could be upgraded to >99.9% if required by a simple re-slurry process in \( n \)-heptane.\(^\text{10} \) The analogous reaction using \( \text{AgOAc} \) would have required 267 g of the silver salt, worth £840, and would have generated 376 g of waste in the form of \( \text{AgI} \).\(^\text{16} \) Excluding costs associated with waste streams, this new process represents savings of ca. 70%. We are confident that our \( \text{NMe}_2 \)-promoted methodology could be readily carried out on multi-kilogram scale.

Conclusions

In summary, we have described the discovery of an organic analogue of silver(I)-salts, and develop reaction conditions that allow the \( \text{Pd} \)-catalysed C–H coupling reaction of a variety of classes of substrates: benzoic acids, benzamides, 2-phenylpyridines, benzoquinolines, indoles, thiophenes, polyfluorobenzenes and 8-methylquinolines with diverse substituted iodoarenes under silver-free conditions. The new method is easily scalable and benefits from the use of inexpensive and readily available reactants, an operationally simple procedure, high functional group tolerance and low-toxicity waste. We believe that this discovery will provide a pathway for facilitating application of numerous existing, and new, direct C–H bond functionalizations to industry, in addition to opening the door to other novel silver-free transition metal catalysed processes.

Notes and references

15 Recently, Yu and co-workers have identified a viable alternative for catalyst regeneration in iodonium reactions by the effective combination of a specific amide auxiliary and CsOAc as iodide scavenger, see: (a) X.-C. Wang, Y. Hu, S. Bonacorsi, Y. Hong, R. Burrell and J.-Q. Yu, J. Am. Chem. Soc., 2013, 135, 10326. Earlier studies on halogenation of C–H bonds showed that Pd(OAc)2 can be obtained from PdI2 with IoAc. This iodonium(I) reagent is not suitable for silver-free arylations as it has to be preformed from AgOAc or Phl(OAc)2 in situ, see: (b) D.-H. Wang, X.-S. Hao, D.-F. Wu and J-Q. Yu, Org. Lett., 2006, 8, 3387; (c) T.-S. Mei, R. Giri, N. Maqović and J-Q. Yu, Angew. Chem. Int. Ed., 2008, 47, 5215; (d) T.-S. Mei, D.-H. Wang and J-Q. Yu, Org. Lett., 2010, 12, 3140.

16 The reaction performed best under neat conditions but some organic solvents are also tolerated. For example, running the reaction 1 M in dioxane, EtOAc or PhCl led to 64%, 53% and 46%, respectively. See Table S1 in the ESI for more details.† J. Palomo and P. N. Pintumo, J. Membrane Sci., 2003, 215, 103.

17 Based on Sigma-Aldrich catalogue prices (April 2014), NMe2CI costs £10.5/ml whereas AgOAc costs £52.6/ml. NMe2I was isolated from the reaction mixture by filtration and characterized, see ESI.†

18 In addition, work-up of reaction mixtures is more difficult when silver is present in the system due to its poor filtration properties. Also, recycling of metal catalysts is hampered by the presence of other metals in the waste, see: (a) E. Jimenez-Nuñez and A. M. Echarvarren, Chem. Rev., 2008, 108, 3326; (b) H. Schmidtbar and A. Schier, Z. Naturforsch., 2011, 66b, 329.
