This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
Spectral shifting and NIR down-conversion in Bi$^{3+}$/Yb$^{3+}$ co-doped Zn$_2$GeO$_4$

Guojun Gao$^1$, Mingying Peng$^{2,3}$ and Lothar Wondraczek$^{1,3*}$

We report on spectral modification through NIR down-conversion (DC) photoluminescence (PL) in Yb$^{3+}$-Bi$^{3+}$-co-doped Zn$_2$GeO$_4$. Energetic downshifting (DS) of UV-A irradiation occurs via intrinsic luminescence of the high-bandgap semiconductor Zn$_2$GeO$_4$ as well as via active Bi$^{3+}$ centres. In parallel, both species act as sensitizers for Yb$^{3+}$, strongly extending its excitation region to ~500 nm. In the absence of Bi$^{3+}$, band-to-band absorption of Zn$_2$GeO$_4$ in the UV region results in PL at ~475–625 nm. Doping with Yb$^{3+}$ initiates energy transfer from trapped defect states to two neighbouring Yb$^{3+}$ ions in a cooperative DC process, resulting in Yb$^{3+}$-related photoemission at ~1000 nm. The introduction of Bi$^{3+}$ into Zn$_2$GeO$_4$:Yb$^{3+}$ greatly extends the absorption band to the visible blue region. Then, energy transfer also occurs through cooperative DC from Bi$^{3+}$ to Yb$^{3+}$. As a result, a strong increase in the absolute Yb$^{3+}$-related PL intensity is observed. This enables ultra-efficient harvesting of UV-A to visible radiation for energy conversion processes.

Introduction

The spectral conversion of incident sunlight through photoluminescence has been proposed to enhance the efficiency of various solar energy harvesting processes.$^{1-7}$ For example, in the case of crystalline silicon solar cells, a large fraction of the incoming solar energy is lost either because photons do not surpass the energy gap which is necessary to generate a photoelectron (NIR-tail of the solar spectrum), or because their excess energy causes thermalization or electron-hole recombination (near-UV to green part of the solar spectrum). Conversion strategies consequently follow some straightforward schemes: for example, in up-conversion processes (UC), two or more low-energy photons are used to generate one photon of higher energy. In down-shifting (DS) or quantum cutting (QC) processes, on the other side, a high-energy photon is converted into one (DS) or more (QC) photons of lower energy.$^{1,2,8-12}$ In the latter, a quantum efficiency which is theoretically higher than unity can be achieved. As a concept, all three processes enable to adjust the incoming solar spectrum through increasing the number of photons within a certain spectral region. Whether or not this is advantageous for a specific solar energy conversion process, however, depends on many other factors, including quantum efficiency, secondary absorption processes, converter properties, system design and cost.

Here, we concentrate on the model system of Zn$_2$GeO$_4$:Yb$^{3+}$ and its further sensitization with Bi$^{3+}$ co-dopants. Yb$^{3+}$ has a rather simple band structure with the single excited state of $^2$F$_{5/2}$ at an energy of ~1 eV. Yb$^{3+}$ photoluminescence therefore occurs at a wavelength of ~1000 nm, which is very close to the maximum photoelectronic conversion efficiency of silicon. Hence, trivalent ytterbium is an often-sought emitter for solar spectral conversion through QC or DS.$^{1,4}$ For this, a suitable sensitizer is required which adds favourable absorption properties to the emission behaviour of Yb$^{3+}$.

Most of the trivalent rare earth (RE$^{3+}$) ions, e.g., Pr$^{3+}$, Eu$^{3+}$, Nd$^{3+}$, Ho$^{3+}$, Tb$^{3+}$, Tm$^{3+}$ and Dy$^{3+}$ have been considered for this purpose.$^{1,2,8-10}$ However, the parity-forbidden 4f$^0$ → 4f$^1$ transitions in these ions typically result in weak and narrow absorption bands which stand in contrast to the wish for efficient (broadband) harvesting of sunlight. As alternatives, ions such as Ce$^{3+}$, Eu$^{2+}$, Bi$^{3+}$ and Mn$^{2+}$, and/or combination with intrinsic absorption of the host itself (e.g., YVO$_4$ and ZnO) have therefore been studied for Yb$^{3+}$ sensitization.$^{20-24}$

The orthogermanate of zinc, Zn$_2$GeO$_4$, is a wide-bandgap semiconductor with a gap-energy of ~4.68 eV.$^{25}$ Without further dopants, it exhibits broadband luminescence in the blue to green spectral region which originates from the recombination of native structural defects.$^{26-27}$ Emission from Zn$_2$GeO$_4$ occurs at about twice the energy which is necessary to excite Yb$^{3+}$: $^3$P$_{0,2} → ^1$F$_{2,3}$. This means that it can be used to sensitize Yb$^{3+}$. On the other hand, absorption covers only the UV region of ~250 to 350 nm, which prevents efficient solar harvesting. To overcome this, we introduce trivalent bismuth as further activator into the Zn$_2$GeO$_4$ host. Bi$^{3+}$ has a 6$s^2$ electronic configuration with ground state $^1$S$_0$ and the excited state 6s6p which splits into the $^1$P$_0, ^3$P$_1, ^3$P$_2$ and $^1$S$_1$ levels. The emission band of Bi$^{3+}$ is typically located in the blue or green, originating from the ligand-field dependent relaxation of $^3$P$_1 → ^1$S$_0$.$^{28-36}$ Although the absorption band of $^1$S$_0 → ^3$P$_1$ is spin-forbidden, it shows reasonably high oscillator strength due to spin-orbit coupling between the $^3$P$_1$ and the $^3$P$_0$ level.$^{12,35}$ Similar to Zn$_2$GeO$_4$, the absorbed energy of Bi$^{3+}$ can probably be transferred to Yb$^{3+}$ through DC processes. Introduction of Bi$^{3+}$ into Zn$_2$GeO$_4$:Yb$^{3+}$ is therefore expected to enable broadband activation of Yb$^{3+}$ NIR photoluminescence.

Experimental Section

This journal is © The Royal Society of Chemistry 2013
Powder samples and compacted pellets with nominal compositions of Zn$_{1.996}$GeO$_2$Yb$_{0.002}$Bi$_{3+}$ ($x$=0, 0.006, 0.02, 0.06 and 0.18 and is the number of Zn$^{2+}$ which is displaced by Bi$^{3+}$ in Zn$_2$GeO$_4$) were synthesized through conventional high-temperature solid state reaction. For that, ZnO, GeO$_2$, Bi$_2$O$_3$ and Yb$_2$O$_3$ (≥4N) were used as starting materials. Stoichiometric batches of ~2 g were thoroughly mixed in an agate mortar, pre-calcined at 900 °C for 4 h in air, again ground in an agate mortar, pressed into pellets and finally fired in air at 1300 °C for 12 h.$^{20}$ Blank (Zn$_2$GeO$_4$) and singly-doped (Zn$_{1.996}$GeO$_2$Bi$_{0.02}$) samples were prepared in the same way for reference.

Powder X-ray diffraction (XRD) patterns were obtained on a Siemens Kristalloflex D500 diffractometer over a 2θ range of 10–70°. UV–vis diffuse reflectance (DR) spectra were recorded with a double-beam photospectrometer (Cary 5000) over the spectral range of 200 to 800 nm with 1 nm step size. Static photoluminescence (PL) spectra and dynamic decay curves were collected at room temperature with a high-resolution spectrophotometer (Horiba Jobin Yvon Fluorolog FL3-22), using a static 450 W Xe lamp and a pulsed 75 W Xe flashlamp as excitation sources, respectively. NIR PL was observed with an InP/InGaAs-based thermoelectrically cooled photomultiplier tube (NIR-PMT, Hamamatsu H10300A-75). PLE spectra were measured between 250 to 500 nm with a step size of 1 nm. PL spectra were recorded between 390 and 700, and 930 and 1200 nm with a step size of 1 nm. PLE spectra were corrected over the lamp intensity with a silicon photodiode. PL spectra were corrected with the spectral response of employed PMT.

Results and discussion

Figure 1a displays in situ powder XRD patterns of Zn$_{1.996}$GeO$_2$Yb$_{0.002}$Bi$_{3+}$ ($x$=0, 0.006, 0.02, 0.06 and 0.18) in dependence of Bi$^{3+}$ doping concentration. Tabulated standard diffraction patterns of Zn$_2$GeO$_4$ and Bi$_4$(GeO$_4$)$_3$ are shown for reference. The unit cell crystal structure of Bi$_4$(GeO$_4$)$_3$ with [ZnO$_2$][BiO$_3$] and [GeO$_3$] tetrahedra is also shown.

Figure 1. (a) Ex situ powder XRD patterns of Zn$_{1.996}$GeO$_2$Yb$^{3+}$Bi$_{3+}$ ($x$=0, 0.006, 0.02, 0.06 and 0.18) in dependence of Bi$^{3+}$ doping concentration. Tabulated standard diffraction patterns of Zn$_2$GeO$_4$ and Bi$_4$(GeO$_4$)$_3$ are shown for reference. The unit cell crystal structure of Zn$_2$GeO$_4$ JCPDS card no. 01-018-0595 (cubic I4, JCPDS card no. 01-084-0505) can also be indexed at $x>0.06$. The unit cell crystal structure of Zn$_2$GeO$_4$ and Bi$_4$(GeO$_4$)$_3$ is shown in Fig. 1b and 1c, respectively. The crystal structure of willemite-type Zn$_2$GeO$_4$ belongs to space group R$ar{3}$ (No. 148). It is comprised of corner-sharing [ZnO$_4$] and [GeO$_4$] tetrahedra (Fig. 1b). While the incorporation of Bi$^{3+}$ into the crystal lattice is expected to result in a change of lattice parameters and in decreasing symmetry (assumedly due to the parallel formation of oxygen vacancies which is necessary for charge compensation), we do not observe a notable shift in the diffraction peaks. This indicates the very low solubility of Bi$^{3+}$ ions in Zn$_2$GeO$_4$ which can be understood on the basis of the large difference in ionic radii between Bi$^{3+}$ and Zn$^{2+}$ or Ge$^{4+}$. The ionic radii of Zn$^{2+}$ and Ge$^{4+}$ in fourfold coordination are 0.60 and 0.39 Å, respectively.$^{35}$ There is no clear data available on fourfold-coordinated Bi$^{3+}$, though. For fivefold coordination, it is 0.96 Å, a significant 60 % higher than the 1.52Zn$^{2+}$ radius. The appearance of the secondary crystal phase is a consequence of this low solubility of Bi$^{3+}$ ions in Zn$_2$GeO$_4$. Eulytite-type Bi$_4$(GeO$_4$)$_3$ is composed of [BiO$_3$] octahedra and [GeO$_3$] tetrahedra (Fig. 1c). It is known as scintillator material and - due to the $^{11}$Bi$^{3+}$-site - is an excellent host for optically active dopants.$^{38,39}$

Figure 2 exemplary shows DR spectra of blank Zn$_2$GeO$_4$ and Bi$_4$(GeO$_4$)$_3$ ($x$=0.02) singly-doped Zn$_2$GeO$_4$. The blank Zn$_2$GeO$_4$ sample exhibits a broad absorption band in the UV region, i.e., from ~200 to 360 nm. This absorption band can be deconvoluted in at least two contributions: an intense band at ~200–290 nm and a weaker shoulder at ~290–360 nm. The intense absorption band is ascribed to contributions: an intense band at ~200–290 nm and a weaker shoulder at ~290–360 nm. The intense absorption band is ascribed to electronic transitions from the valence band to the conduction band of Zn$_2$GeO$_4$ host, whereas the origin of the weaker shoulder is not clear.$^{50}$ From the absorption edge in UV region at ~263 nm, we estimate a band-gap energy of ~4.71 eV which is good accordance with reported data.$^{25,40}$ Addition of Bi$^{3+}$ adds a strong yellow absorption band (originating from the allowed transition of $^{1}$S$_0$ $\rightarrow$ $^{1}$P$_1$ in trivalent bismuth), shifting the UV-edge to ~450 nm. As already mentioned, Zn$_2$GeO$_4$ is a self-activated phosphor. In Figs. 3a-b, we show the room-temperature PLE and PL spectra of blank Zn$_2$GeO$_4$. PLE occurs in a strong band from 250 to 280 nm.
and another, weaker band from 280 to 375 nm, which is consistent with the DR spectra shown in Fig. 2. The excitation maximum locates at ~270 nm which correspond-well with the band gap energy of pure Zn$_2$GeO$_4$. Under UV excitation at 270 nm, PL occurs in the spectral region of ~475–625 nm with a maximum at ~540 nm with a full width at half maximum (FWHM) of ~1647 cm$^{-1}$ (~48 nm) (Fig. 3b). This PL band is assigned to radiative defect-recombination, i.e., a donor ($V_x^*$ and $Zn_x^*$) and an acceptor defect ($V_i$ and ionized $V_{Ge}^*$).$^{27}$ As for effective PL lifetime $\tau_{\text{PL}}$, we find a range < 3 µs (that is, below the pulse length of the employed Xe flash lamp).

Figure 3. (a) Room-temperature PLE ($\lambda_{\text{ex}}$=540 nm) and (b) PL ($\lambda_{\text{em}}$=270 nm) spectra for greenish PL in pure Zn$_2$GeO$_4$. (c) PLE ($\lambda_{\text{ex}}$=976 nm) and (d) PL ($\lambda_{\text{em}}$=270 nm) spectra of Yb$^{3+}$:Zn$_2$GeO$_4$ ($0.02$ mol-% Yb$^{3+}$). The inset of (d) presents the Stark splitting energy levels of Yb$^{3+}$ from the best fit of the PL spectrum of Yb$^{3+}$. The dashed and solid lines in (d) represent the individual Gaussian functions and total fit of the spectra, respectively, as used for deconvolution.

Room-temperature PLE and PL spectra of Yb$^{3+}$ in Yb$^{3+}$ singly-doped Zn$_2$GeO$_4$ are provided in Figs. 3c-d. The PLE spectrum is very similar to the spectrum of pure Zn$_2$GeO$_4$ (Fig. 3a) and also corresponds to the DR spectrum (Fig. 2), showing the aforementioned two contributions at 250-290 nm and 290-375 nm. This directly evidences PL activation of Yb$^{3+}$ through energy transfer from the Zn$_2$GeO$_4$ host. The corresponding NIR PL covers a broad spectral region of 930–1100 nm with a sharp peak at 976 nm and two red-shifted shoulders. The PL spectrum can best be deconvoluted into three Gaussian functions with maxima at 976, 1001 and 1055 nm (as shown in Fig. 3d). Since neither Bi$^{3+}$ nor the Zn$_2$GeO$_4$ host are expected to contribute to the NIR emission at this excitation band, the observed NIR PL is assigned to the transition from the lowest Stark level of Yb$^{3+}$: $F_{2,5}$ to the three different Stark levels of the ground state of Yb$^{3+}$: $F_{2,7}$ (inset of Figure 3d). The occurrence of Yb$^{3+}$-related PL after excitation into the conduction band of Zn$_2$GeO$_4$ confirms existence of energy transfer from Zn$_2$GeO$_4$ to Yb$^{3+}$.

Figs. 4a-c present room-temperature PLE and PL spectra of Bi$^{3+}$ in Zn$_{99.98}$GeO$_4$:Bi$^{3+}$($0.002$ mol-% Bi$^{3+}$) for varying values of $x$. In the presence of Bi$^{3+}$, an additional PL band appears in the spectral range of 390 to 500 nm (maximum at 420 nm, FWHM ~4325 cm$^{-1}$, excitation at 350 nm). This is ascribed to the transition of Bi$^{3+}$: $P_1 \rightarrow S_0$ (Fig. 4c). The Stokes-shift of this Bi$^{3+}$-related PL is relatively low, i.e., ~5200 cm$^{-1}$.$^{29}$ With increasing Bi$^{3+}$ concentration, the intensity of the Bi$^{3+}$-related PL is found to decrease as a result of concentration quenching effect (inset of Fig. 4c).$^{41,42}$ The corresponding PLE spectra exhibit two distinct bands, i.e., from 250 to 290 nm and from 310 to 390 nm, with peaks at ~250 and 345 nm, respectively (Fig. 4a). The high-energy part is ascribed to the extrinsic PLE band of the aforementioned transition from the valence to the conduction band of Zn$_2$GeO$_4$, which suggests the energy transfer from the Zn$_2$GeO$_4$ host to Bi$^{3+}$. The latter contribution is assigned to the intrinsic transition of Bi$^{3+}$: $S_0 \rightarrow P_1$. Under extrinsic excitation through the Zn$_2$GeO$_4$ host (270 nm), the overlapping PL bands the Bi$^{3+}$ active center and the Zn$_2$GeO$_4$ host itself can be observed simultaneously with peaks at ~450 and ~525 nm, respectively (Figs. 4b-d). The overall PL spectrum therefore spans the very broad spectral region of 390–650 nm with a FWHM of ~4020 cm$^{-1}$ (~160 nm). The maximum PL intensity of Bi$^{3+}$: $P_1 \rightarrow S_0$ is found for $x$=0.06, whereas PL from the Zn$_2$GeO$_4$ host is quenched with increasing concentration of Bi$^{3+}$, again confirming the occurrence of energy transfer from Zn$_2$GeO$_4$ to Bi$^{3+}$. It is further observed that under extrinsic excitation through Zn$_2$GeO$_4$, the PL peak which is attributed to Bi$^{3+}$: $P_1 \rightarrow S_0$ shifts to longer wavelength, i.e., from ~420 to 450 nm, as compared to intrinsic excitation of Bi$^{3+}$ centers. This evidences the occurrence of energy transfer from Zn$_2$GeO$_4$ to Bi$^{3+}$ through the defect level of Zn$_2$GeO$_4$ ($V_x^*$ and $Zn_x^*$). As with the intrinsic luminescence from the Zn$_2$GeO$_4$ host, the effective lifetime of the Bi$^{3+}$: $P_1 \rightarrow S_0$ emission is ~3 µs.

Figure 4. Room-temperature PLE ($\lambda_{\text{ex}}$=420 nm), PL (b) ($\lambda_{\text{em}}$=270 nm and (c) normalized PL ($\lambda_{\text{em}}$=270 nm; normalized to the PL peak at 450 nm) spectra of Zn$_{99.98}$GeO$_4$:Bi$^{3+}$ ($x$,=0.006, 0.02, 0.06 and 0.18) as a function of Bi$^{3+}$ doping concentration. The insets of (b) and (d) show PL peak intensity in Zn$_{99.98}$GeO$_4$:Bi$^{3+}$, phosphors versus Bi$^{3+}$ doping concentration. The drawn lines in the inset of (b) and (c) are to guide the eye.

Room-temperature PLE (monitoring Yb$^{3+}$: $F_{2,5} \rightarrow F_{2,7}$ PL at 976 nm) and PL (through extrinsic excitation through the Zn$_2$GeO$_4$ host at 280 nm and through the Bi$^{3+}$ band at 365 nm, respectively) spectra of Zn$_{99.98}$GeO$_4$:Bi$^{3+}$, are shown in Figs. 5a-c. The PLE bands of the Zn$_2$GeO$_4$ host (250 to 315 nm) as well as of the Bi$^{3+}$ active center (345 to 450 nm) can be identified in the PLE spectra of Yb$^{3+}$ (Fig. 5a). This clearly confirms that energy transfer occurs from those entities to Yb$^{3+}$. The typical Yb$^{3+}$-related NIR emission can consequently be observed either through excitation of the Zn$_2$GeO$_4$ host (270 nm) or through excitation of Bi$^{3+}$: $S_0 \rightarrow P_1$ (365 nm, Figs. 5b-c). When excited at 270 nm, the introduction of a small
amount of Bi$^{3+}$ ($x=0.06$) strongly enhances the PL intensity of Yb$^{3+}$ (here: more than 12 times, Fig. 5b), whereas higher Bi$^{3+}$ concentration results in quenching of the Yb$^{3+}$-related PL. Similarly, when excited at 365 nm (i.e., on the Bi$^{3+}$ band), the PL intensity of Yb$^{3+}$ attains a maximum for $x=0.06$ (Fig. 5c).

Figs. 5d-e represent normalized decay curves of Yb$^{3+}$: $^{2}F_{5/2} \rightarrow ^{2}F_{7/2}$ PL at $\lambda_{ex}=976$ nm for excitation through the Zn$_2$GeO$_4$ host and through Bi$^{3+}$, respectively. All decay curves deviate from a single-exponential form, which is related to the different mechanisms of energy transfer, and eventually also to the presence of various types of Bi$^{3+}$-related emission species (where the above-noted optimal dopant concentration coincides with the onset of Bi$_2$(GeO$_4$)$_3$ formation (Fig. 1). The effective lifetime $\tau_1$ of Yb$^{3+}$: $^{2}F_{5/2} \rightarrow ^{2}F_{7/2}$ PL increases with increasing Bi$^{3+}$ concentration from ~90 to 620 µs for excitation through the host (Fig. 5d). When excited through Bi$^{3+}$ species, it first increases from 290 to 510 µs for a Bi$^{3+}$ concentration up to ($x=0.02$). For higher Bi$^{3+}$ dopant concentration, a saturation is found (Fig. 5e and inset of Fig. 5e).

The overall scheme of spectral conversion in Zn$_2$GeO$_4$:Bi$^{3+}$, Yb$^{3+}$ is illustrated in Fig. 6 and compared to the solar irradiance spectrum. Without Bi$^{3+}$, only photons in the spectral region below 350 nm (which accounts for only a small portion of the total solar irradiance) can be harvested. In this case, conversion occurs through intrinsic emission as well as through Yb$^{3+}$ emission centers in the spectral regions of 475–625 nm (green) and 930–1100 nm (NIR). The introduction of Bi$^{3+}$ strongly enhances the spectral harvesting efficiency through extending the absorption band to up to 450 nm. DS PL from both Bi$^{3+}$ and Zn$_2$GeO$_4$ then spans a broad region in the blue-to-red spectral range. Through energy transfer from Zn$_2$GeO$_4$ to Yb$^{3+}$ via Bi$^{3+}$ as well as directly from Bi$^{3+}$ to Yb$^{3+}$, notable conversion to the NIR region can be obtained. In this way, Yb$^{3+}$-emission is activated over the excitation region of 250–500 nm.

This process is summarized in Fig. 7 which depicts the energy level diagrams of the Zn$_2$GeO$_4$ host, Bi$^{3+}$ and Yb$^{3+}$, and schematic illustration of the energy transfer mechanisms from the Zn$_2$GeO$_4$ host to Yb$^{3+}$, from the Zn$_2$GeO$_4$ host to Yb$^{3+}$ via Bi$^{3+}$ and from Bi$^{3+}$ to Yb$^{3+}$ (CET: cooperative energy transfer; ET: energy transfer; MET: multi-phonon-assisted energy transfer).

Figure 5. Room-temperature PLE ($\lambda_{em}=976$ nm) and PL (upon excitation of (b) Zn$_2$GeO$_4$ host at $\lambda_{ex}=280$ nm and (c) of Bi$^{3+}$ at $\lambda_{ex}=365$ nm) spectra for NIR PL from Yb$^{3+}$ emission in Zn$_{1.998-x}$GeO$_4$:Yb$^{3+}$,Bi$^{3+}$ ($x=0$, 0.006, 0.02, 0.06 and 0.18) phosphors as a function of Bi$^{3+}$ concentration. Insets (b) and (c) show PL peak intensity of Yb$^{3+}$ in Zn$_{1.998-x}$GeO$_4$:Yb$^{3+}$,Bi$^{3+}$, phosphors in dependence of Bi$^{3+}$ concentration. Normalized room-temperature decay curves for NIR PL from Yb$^{3+}$ at 976 nm under pulsed excitation of at (d) 280 nm (Zn$_2$GeO$_4$ host) and (e) 365 nm (Bi$^{3+}$). Inset of (d) and (e) shows effective lifetime $\tau_{1/2}$ for NIR PL from Yb$^{3+}$ emission as a function of Bi$^{3+}$ concentration. The lines in the insets of (b), (c), (d) and (e) are guides for the eye.

Figure 6. PLE spectrum of Yb$^{3+}$ in Yb$^{3+}$ singly (cyan line) and Yb$^{3+}$/Bi$^{3+}$ co-doped (violet line) Zn$_2$GeO$_4$, and PL spectrum of Zn$_{1.998-x}$GeO$_4$:Yb$^{3+}$,Bi$^{3+}$ phosphors in visible (green line) and NIR (red line) region under excitation at 280 nm. The standard solar spectrum for air mass 1.5 according to ASTM G173-03(2012) is shown in the background for reference.

Figure 7. Energy level diagrams of Zn$_2$GeO$_4$ host, Bi$^{3+}$ and Yb$^{3+}$, and schematic illustration of the energy transfer mechanisms from the Zn$_2$GeO$_4$ host to Yb$^{3+}$, from the Zn$_2$GeO$_4$ host to Yb$^{3+}$ via Bi$^{3+}$ and from Bi$^{3+}$ to Yb$^{3+}$ (CET: cooperative energy transfer; ET: energy transfer; MET: multi-phonon-assisted energy transfer).
level at ~1000 nm, the energy transfer from Zn$_2$GeO$_4$ host to Yb$^{3+}$ is understood as a second order cooperative DC process. With the introduction of Bi$^{3+}$, the absorption band extends to the blue region. Electrons which are excited into the conduction band of Zn$_2$GeO$_4$ can relax to the defect level of Zn$_2$GeO$_4$ (V$^0_{\text{Ge}}$ and Zn$^+$) and then to the excited level of Bi$^{3+}$; $^3$P$_1$. Alternatively, the excited electrons at conduction band of Zn$_2$GeO$_4$ can directly relax to the excited level of Bi$^{3+}$; $^3$P$_1$ through a multi-phonon-assisted relaxation process. At a small Stokes shift of the Bi$^{3+}$; $^3$P$_1$ level, DS PL from Bi$^{3+}$ can be observed at an emission energy which is a little bit more than twice the absorption energy of Yb$^{3+}$: $^2$F$_{7/2}$ → $^2$F$_{5/2}$. Similar to host excitation, here, energy can be transferred to two neighboring Yb$^{3+}$ in a cooperative DC process to yield Yb$^{3+}$ emissions at ~1000 nm. Under excitation at 365 nm, the electrons are excited from the ground state of Bi$^{3+}$; $^1$S$_0$ to the excited state of Bi$^{3+}$; $^3$P$_1$. The following processes are the same as just described. \[ \text{Conclusions} \]

In conclusion, we discussed the spectral properties of the high-bandgap semiconductor Zn$_2$GeO$_4$ co-doped with Yb$^{3+}$ and Bi$^{3+}$ as a model system for ultra-efficient conversion of the UV-A-blue part of the solar spectrum to the NIR spectral region. We have shown that Yb$^{3+}$-related PL can be activated through intrinsic absorption of the Zn$_2$GeO$_4$ lattice itself, and through Bi$^{3+}$ centers. Energy transfer then occurs via cooperative DC from trapped defect states and from the $^3$P$_1$ level of Bi$^{3+}$. This results in a strong increase in the absolute intensity of Yb$^{3+}$-related PL. The material enables ultra-efficient harvesting of UV-A to visible radiation for energy conversion processes which rely on NIR irradiation such as c-Si photovoltaics and various photochemical processes. \[ \text{Acknowledgement} \]

We report on Zn$_2$GeO$_4$ co-doped with Yb$^{3+}$ and Bi$^{3+}$ as a model system for ultra-efficient down-conversion of the UV-A/blue part of the solar spectrum to the NIR.
