Abstract

In this paper, we reported a novel electrochemical aptamer-antibody based sandwich biosensor for the detection of lysozyme. In the sensing strategy, Anti-lysozyme aptamer was immobilized onto the carbon electrode surface by covalent binding via diazonium salt chemistry. After incubating with the target protein (lysozyme), a biotinylated antibody was used to complete the sandwich format. The subsequent additions of avidin-alkaline phosphatase as enzyme label, and 1-naphthyl phosphate substrate (1-NPP) allowed to determine the concentration of lysozyme (Lys) via Differential Pulse Voltammetry (DPV) of the generated enzyme reaction product, 1-naphthol. Using this strategy, a wide detection range from 1 fM to 5 nM was obtained for target lysozyme, with a detection limit of 4.3 fM. The control experiments were also carried out by using albumin (BSA), cytochrome c and casein. The results showed that the proposed biosensor had good specificity, stability and reproducibility for lysozyme analysis. In addition, the biosensor was applied for detecting lysozyme in spiked wine samples, very good recovery rates were obtained in the range from 96.67 to 102% for lysozyme detection. This implies that the proposed sandwich biosensor is a promising analytical tool for the analysis of lysozyme in real samples.

Keywords: aptamer-antibody sandwich, biosensor, lysozyme detection, differential pulse voltammetry, wine sample

1. Introduction

Nowadays, use of biosensors for detection and quantification of proteins plays a vital role in research¹, clinical applications² and food industry³. Biosensors are analytical devices which incorporate a biomolecule to provide specific recognition for an analyte together with transduction technology to detect and quantify the binding taking place between analyte and detector molecule⁴. Traditionally, enzymes, antibodies and proteins have been employed in biosensors as biorecognition species. Since their discovery in 1990⁵, aptamers have attracted considerable attention in biosensor development⁶. Aptamers are artificial DNA or RNA oligonucleotides selected *in vitro* which have the ability to bind to proteins, small molecules or even whole cells, with high affinity and specificity⁷. They offer many advantages over antibodies such as relatively easy production, highly affinity and specificity, easy chemical modification and high stability⁸. Thanks to these excellent properties, a number of aptamer-based sensors have been developed using different transducer techniques^{9, 10}. Among different types of biosensors, electrochemical biosensing is of particular interest due to its remarkable sensitivity, simple instrumentation, fast response, low cost and portability¹¹.

Lysozyme (Lys) is a relatively small protein (14.3 kDa) consisting of only 129 amino acid residues, and is widely distributed in the nature¹². It has an isoelectric point of 11.0 and constitutes 3.5% of egg white protein. It is clear that lysozyme's relatively small size and simplicity makes it an excellent model analyte for novel methods in protein detection. This protein is also known as N-acetylmuramide glycan hydrolase due to its property to destroy bacterial cellular membranes by catalyzing the hydrolysis of glycosidic bonds between N-acetylmuramic acid and N-acetylglucosaminein peptidoglycan residues of Gram-positive bacteria cell walls¹³. Moreover, the monitoring of lysozyme level is used as a marker of some health problems such as

1
2
3 bronchopulmonary dysplasia in newborns¹⁴, conjunctivitis, kidney problems¹⁵ and
4 leukemia¹⁶. Additionally, Lys has been widely used as an antimicrobial agent in the
5 production of wine¹⁷, cheese¹⁸, beers¹⁹ and as well as to prolong the shelf-life of shrimp,
6 surimi products and sausages²⁰. Specifically, in wine-making, Lys has been used since
7 1990 to prevent or mitigate heterolactic fermentation¹⁷. The maximum permitted level
8 of lysozyme in wine samples is 500 mg/L ($\sim 35\mu\text{M}$)²¹. Being an egg-protein, lysozyme
9 is considered as an allergen; therefore developing new, rapid, cheap and sensitive
10 methods for the detection of Lys is of great significance.

20
21 Presently, the available analytical methods for the detection of lysozyme include
22 conventional methods like chromatographic or immunosensing techniques based on
23 ELISA, which have high sensitivity, but high cost and experimental complexity. Thus,
24 numerous sensors have been presented as alternatives to overcome these limitations
25 based on mainly electrochemical, surface Plasmon resonance and optical detection^{22, 23}.
26 In this work, we report a novel electrochemical aptamer-antibody sandwich assay for
27 the detection of Lys. Differential Pulse Voltammetry (DPV) technique was used to
28 detect Lys via 1-naphtol oxidation signal changes. For this purpose, the aptamer was
29 immobilized onto the electrode surface by covalent binding via diazonium salt. After
30 incubating with lysozyme, a biotinylated antibody was used to form the sandwich
31 format. The addition of avidin modified alkaline phosphatase and the 1-NPP enzymatic
32 substrate allowed to detect lysozyme based on the electrochemical oxidation signals of
33 1-naphtol. Results showed that this novel biosensor can be used for accurate
34 quantification of the concentration of Lys in spiked wine samples. The developed
35 biosensor is simple, sensitive, specific and fast for the detection of Lys.

55 **2. Experimental**

56 *2.1. Chemicals and materials*

Potassium dihydrogen phosphate, sodium monophosphate, bovine serum albumin (BSA), lysozyme (Lys), avidin-labeled alkaline phosphatase (Av-ALP), casein, biotin-labeled rabbit anti-chicken Lys antibody (AbLysBio), magnesium chloride, potassium chloride, sodium chloride, ethanolamine, diethanolamine (DEA), N-hydroxysuccinimide (NHS), N-(3-dimethylaminopropyl)-N'-ethyl-carbodiimide hydrochloride (EDC), 4-aminobenzoic acid (ABA), 1-naphthyl phosphate (1-NP) and sodium nitrite were purchased from Sigma (St. Louis, MO, USA). All reagents were analytical reagent grade. The aptamer used was:

AptLysCOX²⁴

5'-NH₂-GCA GCT AAG CAG GCG GCT CAC AAA ACC ATT CGC ATG CGG C-3'
and was provided by Eurogenetic (France)

All solutions were made up using MilliQ water. The buffers employed were: binding buffer (BB) (1mM MgCl₂, 2.7mMKCl, 140mMNaCl, 0.1mM Na₂HPO₄ and 1.8mMKH₂PO₄ pH 7.4), 10% DEA buffer (pH 9.5) and 100mM MES buffer containing 0.09%NaCl.

2.2. Equipment

The electrochemical measurements were performed using an Autolab PGSTAT100 potentiostat/galvanostat (Eco Chimie, Netherlands) controlled by General Purpose Electrochemical System software (GPES) (4.9) for voltammetry. Screen printed carbon electrodes (SPCEs) were fabricated using a DEK 248 screen-printing system. The SPCE consists of conventional three electrode configuration with graphite as working (4-mm diameter disk) and counter (16 mm × 1.5 mm curved line) electrode, and Ag/AgCl (16 mm × 1.5 mm straight line) as pseudo reference electrode.

2.3. Experimental protocol

2.3.1. Electrochemical SPE pretreatment

SPE was subjected to electrochemical pretreatment by 10 cyclic potential scans between 1.0 and -1.5V at scan rate of 0.2V/s in 0.5M H₂SO₄ and 0.1M KCl. Then, the electrodes were rinsed with water.

2.3.2. Immobilization of AptLys onto the electrode surface

In detail, the diazonium cation was synthesized by in situ reaction of 2 μ L of 1M NaNO₂ and 1mL of 2mM ABA prepared in 0.5M HCl. The mixture was left to react for 5 min at room temperature. 100 μ L of this mixture and 100 μ L of 0.5M HCl were deposited onto the electrode surface and the electrochemical modification was performed by linear sweep voltammetry from 0.6 to -0.8V. After modification, the electrode was rinsed three times with distilled water. Linear voltammetry was used for surface modification to avoid the multilayer formation, and to have a uniform monolayer on the electrode surface. As the thickness of the layer and blocking effect are related to diazonium reduction, electrodes with same magnitude of reduction peak for diazonium were used to immobilize the aptamer. The carboxylic groups onto the electrode surface were activated with 100 μ L of 100mM EDC and 25mM NHS in 100mM MES buffer for 1 hour. After rinsing three times with distilled water, 30 μ L of 10 μ M solution of Apt were incubated onto the electrode surface for 1 hour. After that, the electrodes were washed three times with BB to remove the unbound aptamer. In order to deactivate the remaining succinimide groups, the electrodes were incubated with 30 μ L of 1M ethanolamine solution. After washing three times with BB, the electrodes were incubated with 30 μ L of 5% BSA solution for 1h to avoid nonspecific adsorption. The modified electrodes can be used directly or stored dry at 4°C for several days without decrease in the sensitivity.

2.3.3. Aptamer-antibody sandwich assay

1
2
3 The electrodes were incubated with different concentrations of Lys for 15 min. Then,
4
5 the electrodes were washed three times with BB. In order to achieve the aptamer-
6
7 antibody sandwich, the electrodes were incubated with 30 μL of anti-Lys antibody from
8
9 a 1/1500 dilution of the stock solution in BB buffer. The incubation took place for 1 h.
10
11 This was followed by three washing steps using BB. Then, 30 μL of av-ALP, from
12
13 1/12500 dilution from the stock solution of enzyme, were deposited on the electrodes
14
15 for 1 h. After that, the electrodes were washed three times with BB.
16
17

18 *2.3.4. Electrochemical detection*

19
20
21 90 μL of 10% DEA buffer and 10 μL of 1-NPP $5\text{mg}\cdot\text{mL}^{-1}$ were added on the electrode
22
23 surface and incubated for 2 min at room temperature. Electrochemical detection was
24
25 performed by DPV. A modulation time of 2s, interval time of 0.2 s, initial potential of
26
27 0.1V, end potential of 0.4V, step potential of 0.01V, modulation amplitude of 0.06V
28
29 and stand-by potential of 0 V were applied. The height of the resulting oxidation peak
30
31 was recorded and plotted against Lys concentration to give a calibration curve.
32
33
34

35 *2.3.5. Wine samples preparation*

36
37 Wine samples were prepared following a protocol from a previous study²³. Briefly, 1
38
39 mL of wine sample was spiked with 200 μM of Lys and allowed to stand for 3 min. Next,
40
41 200 μL of a 5M NaCl solution containing 5% Tween-20 surfactant were added to 200 μL
42
43 of lysozyme-wine mixture and diluted to a final volume of 1 mL using 20 mM MES
44
45 buffer pH 6 with 1 mM MgCl_2 . This mixture was further centrifuged at 5000 rpm for
46
47 5 min and diluted using the buffer aforesaid to obtain the desired concentration of Lys.
48
49

50 **3. Results and discussion**

51 *3.1. Principle of the aptamer-antibody sandwich assay*

52
53
54
55
56
57
58
59
60

1
2
3 Figure 1 illustrates the different steps involved in the fabrication of biosensor for the
4
5 detection of Lys based on its specific recognition by aptamer-antibody assay. As
6
7 described in Section 2.3, the aptamer was covalently immobilized through EDC/NHS
8
9 chemistry via diazonium salt on the SPE surface. This step was followed by a blocking
10
11 step with BSA to avoid non-specific adsorption on the transducer surface. Then, Anti-
12
13 Lys antibody was incubated on the sensing platform to obtain sandwich type detection.
14
15 Thereafter, a solution of avidin modified-ALP was deposited onto the electrode surface
16
17 to achieve coupling to the antibody through biotin-avidin affinity. Finally, the biosensor
18
19 was immersed in DEA buffer solution of pH 9.5 containing 1-NPP as ALP substrate,
20
21 and Lys was determined by differential pulse voltammetry of the generated 1-naphtol as
22
23 the enzyme reaction product.
24
25
26

27
28 <Figure 1>
29

30 31 *3.2. Optimization of the working experimental conditions*

32
33 In order to achieve the improved analytical characteristics of a proposed biosensor, it is
34
35 of vital importance to optimize the different experimental parameters. In this context,
36
37 several parameters including pH, temperature conditions, concentrations of anti-Lys
38
39 antibody and avidin modified enzyme, and their incubation time with Lys were
40
41 optimized prior to perform concentration dependence response of the proposed
42
43 sandwich assay. Electrochemical response of the sandwich biosensor was investigated
44
45 for different pH of PBS buffer (6.8-8.2) and under varying temperature conditions. The
46
47 maximum electrochemical output signal was obtained at pH 7.4 under room
48
49 temperature. Figure 2a shows the voltammetric peak response of 1-NPP in the presence
50
51 of different concentrations of Anti-Lys antibody (1/3000 from to 1/500, dilutions from
52
53 stock solution of antibody). As can be observed, the current response increased rapidly
54
55 with increasing concentration of Anti-Lys antibody, with a maximal electrochemical
56
57
58
59
60

1
2
3 output signal at 1/1500. Similarly, Figure 2b shows that peak current increased with
4 increasing concentration of avidin modified ALP till 1/12500 (dilution from stock
5 enzyme solution), which was followed by a decrease in response for subsequent
6 increasing concentration, indicating the saturation point of enzyme label is reached.
7 Thus, 1/1500 and 1/12500 were chosen as the optimal dilutions for Anti-Lys antibody
8 and avidin modified-ALP respectively.
9
10
11
12
13
14
15

16
17 The effect of the incubation time of Lys on the current response of the biosensor
18 was also studied. As can be seen from Figure 2c, the maximum peak current of *I-NPP*
19 was observed for an incubation period of 15 min. For longer incubation times, the peak
20 current was decreased. Thus, according to the experimental results, an incubation time
21 period of 15 min was selected to perform the further experiments.
22
23
24
25
26
27

28 <Figure 2>
29

30 3.3. Analytical performance of the aptamer-antibody sandwich biosensor 31 32

33 In order to perform the quantitative analysis, the designed biosensor was incubated with
34 different concentrations of Lys under the optimal conditions, and the DPV responses
35 were recorded to draw a calibration curve. As shown in the Figure 3a, the oxidation
36 peak current increased with the increasing concentration of Lys. The peak current was
37 plotted against the concentration of Lys, and the calibration plots (Figure 3b) exhibited
38 a good linear correlation between the peak current and the logarithm of Lys
39 concentrations in the range from 5fM to 5nM with a correlation coefficient of 0.998.
40 The calculated limit of detection (LOD) for Lys was 4.3fM. The reproducibility of the
41 method showed a relative standard deviation (RSD) of 5.5%, obtained from a series of 3
42 experiments carried out in a concentration of 5nM of Lys. Table 1 provides a
43 comparison of different biosensors reported in the literature for Lys detection. The data
44 in Table 1 indicates the lowest limit of detection of our proposed sandwich biosensor as
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 compared to the LOD of previously reported biosensors for Lys detection. In addition,
4
5 the linear range was greatly improved, being much wider than for other biosensors. The
6
7 improved analytical performance can be attributed to the use of aptamer as capturing
8
9 probe for analyte on the transducer surface. Aptamers have a unique number of
10
11 characteristic including higher binding affinities, immobilization onto the solid surface
12
13 in a controlled orientation and retention of their conformation upon immobilization.
14
15 Based on the fact that aptamer was used as capturing probe in sandwich format, the
16
17 enhanced analytical performance was expected in the purposed assay as compared to the
18
19 conventional antibody based sandwich format where an antibody is used as capturing
20
21 probe.
22
23

24
25 The aptamer modified transducer surface was observed to retain its electrochemical
26
27 signal after a storage period of 2 weeks at 4 C° with a negligible loss of activity. This
28
29 suggests that the immobilization method has resulted in the improved stability of the
30
31 aptamer, and aptamer modified electrode can be employed as ready to use tool for target
32
33 analyte detection.
34
35

36
37 <Figure 3>
38

39
40 <Table 1>
41

42 43 *3.4. Selectivity of the biosensor* 44

45
46 In order to establish the specificity and selectivity of the designed biosensors, different
47
48 proteins including casein, BSA and cytochrome c were incubated on the biosensor
49
50 surface and DPV measurements were carried out under the same experimental
51
52 conditions as those described for Lys analysis. As shown in Figure 4, the presence of
53
54 these proteins exhibited a negligible response compared with that of Lys, even in the
55
56 case of cytochrome c which is structurally similar to Lys. Therefore, the results
57
58
59
60

1
2
3 demonstrated that the developed strategy could be used to identify Lys with high
4
5 specificity.
6

7 <Figure 5>
8

9 10 3.5. Application of the biosensor for the detection of Lys in spiked wine sample

11
12 In order to demonstrate the analytical reliability and applicability of the method for real
13
14 sample matrix, analysis of wine samples were performed by spiking at three different
15
16 concentrations of Lys (1.5 nM-5 pM). The recovery values were determined in
17
18 accordance with the calibration curve performed in buffer. The obtained Lys
19
20 concentrations were in consistent with the spiked values, indicating the suitability of
21
22 method for real sample analysis. The recovery results along with other analytical
23
24 characteristic for the proposed biosensors are presented in the table 2.
25
26

27 <Table 2>
28

29 30 **Conclusions**

31
32 In conclusion, a novel electrochemical biosensor has been successfully developed for
33
34 the detection of lysozyme protein based on a hybrid sandwich protocol. Differential
35
36 Pulse Voltammetry was used to detect Lys via the changes in 1-naphthol oxidation
37
38 signals. The described biosensor showed a lower detection limit (4.3fM) as compared to
39
40 the previously reported biosensors for lysozyme detection (Table1), wide linear range
41
42 for lysozyme detection from 5 fM to 5nM, high sensitivity and selectivity. In addition,
43
44 the biosensor was used for detecting lysozyme in spiked wine samples and very
45
46 promising recovery values were obtained, indicating the great potential of proposed
47
48 methodology for detecting lysozyme in wines and possibly other food matrices.

Figures and Captions

Figure 1. Schematic representation of the developed sandwich biosensor.

Figure 2. a) Optimization of the concentration of AbLysantibody. b) Optimization of the concentration of fav-ALP. c) Optimization of incubation time with Lys. Uncertainty values corresponding to replicate experiments (n = 3).

Figure 3. a) DPV curves for different concentrations of Lys; b) Calibration curve and regression plot of the biosensor. Uncertainty values corresponding to replicate experiments (n=3).

Figure 4. Selectivity of the biosensor to casein, BSA and cytochrome Cat 5nM, respectively. Error bars are obtained based on three independent measurements.

Tables

Table 1. Comparison of the proposed biosensor with other reported methodologies for lysozyme detection.

Analytical Technique	Detection Limit	Linear Range	Reference
Electroluminescence	120 pM	64pM-0.64μM	25
Electroluminescence	0.15ng·mL ⁻¹ ¹ (~10.4pM)	0.5nM-9nM	26
SPR	2.4nM	0.5-80μg·mL ⁻¹	23
Impedance	6fM	0.01-0.5pM	27
Impedance	28.53nM		28
Impedance	862nM	0-400μg·mL ⁻¹	29
Impedance	0.07nM	0.2nM-4nM	30
Square Wave Voltammetry	0.2nM	0.5nM-100nM	31
Square Wave Voltammetry	38/16nM	0-30mg·L ⁻¹	32
Square Wave Voltammetry	1nM	7-30nM	33
Square Wave Voltammetry	0.3pg·mL ⁻¹ ¹ (~20.8fM)	1-50pg·mL ⁻¹	34
Cyclic Voltammetry	0.1pM	5pM-1nM	35
Differential Pulse Voltammetry	4.3fM	5fM-5nM	Our work

Table 2. Recovery studies performed in spiked wine samples for applicability of biosensor (n=3).

Spiked [Lys] (M)	Found [Lys] (M)	R.S.D.%	Recovery %	Relative error %
$1.5 \cdot 10^{-9}$	$1.45 \cdot 10^{-9}$ $\pm 0.04 \cdot 10^{-9}$	3.1	96.67	3.33
$2.5 \cdot 10^{-11}$	$2.38 \cdot 10^{-11}$ $\pm 0.099 \cdot 10^{-11}$	4.2	95.2	4.8
$5 \cdot 10^{-12}$	$5.1 \cdot 10^{-12}$ $\pm 0.26 \cdot 10^{-12}$	5.1	102	1.96
