Accepted Manuscript

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this *Accepted Manuscript* with the edited and formatted *Advance Article* as soon as it is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

25 **11 Abstract**

26
27 12 DNAzyme based electrochemical biosensor has the characters of high sensitivity
28
29 13 and selectivity, but traditional DNAzyme based electrochemical biosensor need the
30
31 14 immobilization of DNAzyme on the electrode surface first, the procedures are time
32
33 15 consuming and tedious, which limit its real application. In this study, a simple but
34
35 16 sensitive immobilization free DNAzyme based electrochemical biosensor had been
36
37 17 proposed and lead had been chosen as a model target because of the severe effects of the
38
39 18 lead toxicity. The different diffusivity and electrostatic repulsion between long and
40
41 19 short DNA on the negatively charged ITO electrode can be used to discriminate the
42
43 20 short and long DNA. Lead dependent DNAzyme had been hybridized with its
44
45 21 substrate (which had been modified with a methylene blue at 3' terminal) beforehand.
46
47 22 Since the DNAzyme/substrate complex contains large negative charge, which can not
48
49 23 diffuse easily to the negative charged ITO electrode surface and little electrochemical
50
51 24 signal has been detected. The presence of lead would trigger the cleavage of
52
53 25 DNAzyme/substrate complex and cause the releasing of methylene blue-labeled
54
55 26 short-oligonucleotide into the solution. The methylene blue-labeled
56
57 27 short-oligonucleotide can diffuse easily to the surface of the negative charged ITO
58
59 28 electrode and results in the enhanced electrochemical response detected. Each lead
60
29 can cleave a lot of DNAzyme/substrate complex to realize signal amplification. The

1 enhanced electrochemical signal has a linear relationship with the Pb^{2+} concentration
2 in the range of $0.05 \sim 1 \mu\text{M}$ with a detection limit of $0.018 \mu\text{M}$ ($\text{S/N}=3$). The proposed
3 biosensor had been applied to detect Pb^{2+} in water samples with satisfied results.

5 **Keywords:** immobilization free; DNAzyme; electrochemistry; lead; ITO electrode.
6

7 **1. Introduction**

8 DNAzymes, DNA sequences with catalytic activities, are isolated through in vitro
9 selection¹. DNAzyme has the inherent characters such as specificity, versatility,
10 stability, ease of synthesis and modification, which has been applied in various fields
11 including clinical diagnosis², environmental monitoring³, biosensing⁴ and cell
12 imaging⁵. Electrochemical technique has the advantages of low-cost, high sensitivity
13 and can be applied in on-field detection easily; many selective and sensitive
14 DNAzyme based electrochemical biosensors had been developed for versatile
15 targets⁶⁻¹⁰. But until now, nearly all DNAzyme based electrochemical biosensors need
16 the immobilization of DNAzyme on the electrode surface first. The procedures are
17 tedious and time-consuming. Furthermore, the hybridization between the immobilized
18 DNAzyme and the other DNA occurred on the solution-electrode interface, this
19 strategy suffers from the low efficiency because of the spatial hindrance effect of the
20 electrode surface. Third, the immobilized DNAzyme may release from the electrode
21 surface during the long-time storage, which affects the stability and reproducibility of
22 the biosensor. It is necessary to develop an immobilization free system to overcome
23 these drawbacks.

24 Lead-dependent DNAzyme has been paid much attention since lead can cause
25 many side effects to the human health¹¹. Many sensitive DNAzyme based
26 electrochemical biosensors for lead determination had proposed. Xiao et al. proposed
27 a electrochemical sensor of Parts-Per-Billion Lead based on an Electrode-Bound
28 DNAzyme Assembly⁶, where the double-stranded DNA containing the signal probe
29 must be immobilized on the electrode surface first, then the DNAzyme cleaves the
30 substrate by the addition of Pb^{2+} , as a result, the MB to transfer electrons to the

1 electrode. Shen et al. showed an electrochemical method base on catalytic reactions of
2 a DNAzyme upon its binding to Pb^{2+} and the amplification of DNA-Au bio-bar
3 codes¹². Pelossof et al. developed an electrochemical sensing platform for lead based
4 on the amplification mechanism of the immobilization of the sensing complex on Au
5 NPs and the electronic coupling between the NPs and the surface plasmon wave¹³.
6 Yang et al. reported an electrochemical DNAzyme sensor for Pb^{2+} by using
7 Pb^{2+} -specific DNAzyme functionalized gold nanoparticles (AuNPs)¹⁴. But all these
8 sensors need DNA immobilization on the electrodes surface.

9 DNA contains negative charge due to the negative charge phosphate component¹⁵.
10 Early report showed that ITO electrode surface can be negatively charged after simple
11 treatment¹⁶. Since short DNA contains little negative charge while long DNA contains
12 big negative charge, so there has difference electrostatic repulsion between the short
13 DNA and long DNA with the negatively charged surface of ITO electrode. Short DNA
14 can diffuse easily to the negatively charged surface, while long DNA cannot reach the
15 surface easily. This character had been applied to discriminate the short DNA and
16 long DNA with high efficiency, many immobilization free electrochemical biosensors
17 had been proposed based on this character also¹⁷. For example, I-Ming Hsing et al.
18 showed an immobilization-free electrochemical method for Hg^{2+} detection base on
19 exonuclease III activity mediated by Hg^{2+} reshuffling on thymine-rich DNA
20 duplexes¹⁸. Combined with signal amplification tactics, they also developed two
21 immobilization-free electrochemical sensors for DNA detection^{17, 19}. Tang et al.
22 proposed an electrochemical DNA biosensing platform based on an ingeniously
23 designed of exonuclease III-aided autocatalytic two target recycling strategys²⁰. Wei
24 et al. developed an electrochemical sensor for DNA methylation detection and its
25 inhibitor screening based on the fact that Dpn I can cleave long DNA through the
26 recognition site in the presence of DNA methylation²¹. Recently, we reported an
27 ultrasensitive homogeneous DNA electrochemical biosensor based on nicking
28 endonuclease signal amplification (NESA), which exhibits a high distinction ability to
29 single-base mismatch and double-bases mismatch²². These studies showed the
30 convenient of the biosensors based on the negative charged ITO electrode. But till

1
2
3
4 now, the targets for these immobilization free biosensors are mostly focus on DNAs.
5
6 It is necessary to find out some way to expand the application of ITO electrode based
7
8 immobilization free technology.
9

10 To the best of our knowledge, no report which combines the advantages of the
11
12 DNAzyme and the ITO based immobilization free electrochemical biosensors had
13
14 been reported. In this study, a simple and sensitive DNAzyme based immobilization
15
16 free electrochemical biosensor for Pb^{2+} detection had been reported, which combines
17
18 the convenient of the ITO based immobilization free biosensor and high spectivity of
19
20 the DNAzyme. The established biosensor has high selectivity due to the DNAzyme
21
22 and easy operating due to immobilization free, which had been applied to detect the
23
24 lead in water samples with satisfied results.
25

26 27 28 **2. Experimental Section**

29 30 **2.1 Reagents**

31
32 DNAzyme and the methylene blue (MB) labeled substrate strand were
33
34 synthesized by Sangon Inc. (Shanghai, China). Their sequences are shown below:
35
36 5'-AAAAAAAAAACACACCAACCT-rA-GTGACT-(methylene blue)-3' (MB
37
38 labeled substrate); 5'-AGTCATCCGAGCCGGTCGAAAGGTTGGTG GGTGG-3'
39
40 (DNAzyme). Where rA is ribo-adenine. DNA buffers contain 10 mM $MgCl_2$, 50 mM
41
42 NaCl and 50 mmol/L Tris-HCl buffer (pH 7.4). Targeted Pb^{2+} buffers composed of 10
43
44 mM $MgCl_2$, 50 mM NaCl and 50 mmol/L Tris-HCl buffer (pH 7.4). All other
45
46 chemicals were of analytical grade.
47

48 **2.2 Electrochemical determination system and ITO electrode preparation**

49
50 The electrochemical determinations were performed on a CHI660a
51
52 electrochemical system (CH Instruments, Shanghai, China). An ITO electrode had
53
54 been used as working electrode in which effective working electrode area is
55
56 5mm×3mm; two Pt wires had been used as reference electrode and counter electrode
57
58 respectively. The potential of the Pt reference electrode in the buffer was determined
59
60 to be +0.36 V with respect to an Ag/AgCl reference electrode. A negatively charged
ITO working electrode surface can be reached after the treating processes after

1
2
3
4 1 sonication in an alconox solution (10g/L of Alconox of double-distilled water) for 15
5
6 2 min, propan-2-ol for 15 min, and twice in double-distilled water for 15 min in
7
8 3 sequence²³. 1.5mL disposable microcentrifuge tube has been used as the
9
10 4 electrochemical cell.

5 **2.3 DNA hybridization and cleavage of the hybridization product by Pb²⁺**

6 Hybridization of the MB labeled substrate and DNAzyme was conducted
7 through the incubation of substrate (ultimate concentration of 1.0 μM) with
8 DNAzyme (ultimate concentration of 1.5 μM) at 37°C (which is the generally
9 accepted optimal temperature for hybridization and below the unwinding condition of
10 the DNAzyme-substrate complex (T_m = 56.7°C)) in 50 μL of 50 mM Tris-HCl buffer
11 (pH 7.4, 10 mM MgCl₂, 50 mM NaCl) for 2 h. Then different concentrations of Pb²⁺
12 had been added in above solution. Cleavage was executed at 37 °C for 120 min to
13 obtain the maximum cleavage of substrate strand⁶. Then, the differential pulse
14 voltammetry (DPV) signal from the mixture was recorded with a potential interval of
15 0 to -0.6 V. Each sample had been detected five times, the average value had been
16 applied for quantitative analysis.

17 18 **3. Results and discussion**

19 **3.1 Principle of the immobilization free electrochemical biosensor**

20 Fig.1 illustrates the principle of proposed immobilization free DNAzyme based
21 electrochemical biosensor. The Pb²⁺-dependent DNAzyme (“8-17” DNAzyme)
22 employed is a sequence-specific nuclease acting on a single stranded DNA substrate
23 containing a single, sessile ribo-adenine (indicated by the arrow in Fig.1). The
24 substrate strand had been modified with a methylene blue (MB) at the 3'terminal first,
25 and then hybridizes with the DNAzyme to form the DNAzyme/substrate complex.
26 Since the complex contain large negative charge, which cannot diffuse easily to the
27 negative charged ITO electrode surface, so only weak electrochemical signal can be
28 detected. In the presence of Pb²⁺, the DNAzyme catalyzes the hydrolytic cleavage of
29 the substrate sequence into two pieces, one of which contains MB has short single
30 strand DNA (eMB) (only 6-base). And the Pb²⁺ can be applied to trigger the next

1
2
3
4 1 round of substrate strand cleavage and eT releasing. Since eMB contains only short
5
6 2 DNA, the electrostatic repulsion from the negatively charged ITO working electrode
7
8 3 to eT is much little than that of the DNAzyme/substrate complex or substrate, so
9
10 4 which can diffuse easily to the negative charged ITO electrode surface and an obvious
11
12 5 enhancement electrochemical signal can be detected. The specificity of the sensor can
13
14 6 be assured by the high selectivity of the DNAzyme. Thus, a sensitive and selective
15
16 7 immobilization free sensor can be developed.

8 9 **The preferred position for Fig. 1**

10
11 A simple assistant experiment has been performed to verify our presumption. The
12
13 12 interference from Pb^{2+} had been checked first, as shown in Fig.2, no DPV signal
14
15 13 found (line a) if the solution contained only Pb^{2+} . Little electrochemical response had
16
17 14 been recorded in the solution which contained MB labeled substrate (line b) or
18
19 15 DNAzyme/substrate complex (line c). The reason lies in that the MB labeled substrate
20
21 16 contains long negative charged single strand DNA, which limits its diffusion to the
22
23 17 negative charged ITO electrode surface, so only little signal been detected. After
24
25 18 hybridization with the DNAzyme, the complex contains much more negative charge,
26
27 19 so much little signal been detected. But after the addition of Pb^{2+} into
28
29 20 the DNAzyme/substrate complex solution, an obvious enhancement DPV signal had
30
31 21 been detected (line d).The reason lies in that Pb^{2+} can activates the DNAzyme and
32
33 22 induces the cleavage of the substrate sequence into two pieces including methylene
34
35 23 blue-labeled short-oligonucleotide (eMB). eMB can diffuse easily to the ITO
36
37 24 electrode surface since the electrostatic repulsion from the negatively charged ITO
38
39 25 working electrode to eMB is little, so enhanced DPV signal can be detected. These
40
41 26 results confirmed the feasibility of our principle.

42 43 44 45 46 47 48 49 50 51 52 53 54 55 56 57 58 **The preferred position for Fig. 2**

59 60 **3.2 Optimization of reaction conditions**

1 MB labeled substrate plays an important role in performance of the system since
2 an excessive amount of which can lead to the high background signal while low
3 concentration leads to the weak signal detected. So the concentrations of MB labeled
4 substrate had been optimized first, DNAzyme (1.5 μM) and Pb^{2+} (1 μM) were mixed
5 with different concentrations of substrate ranged from 0.2 μM to 2.0 μM . As shown in
6 Fig.3A, the DPV signals of the system increased with the substrate concentration in
7 the range from 0.2 to 1.0 μM and then reached the saturated condition after 1.0 μM .
8 And if the concentration of substrate was higher than 1.2 μM , the background signal
9 would grow. Therefore, 1.0 μM substrate was chosen as the optimized condition for
10 the following experiments.

11 The cleavage time also plays an importance role in the performance of the
12 system. As shown in Fig.3B, the DPV signal increased with the increasing of cleavage
13 time first and then reached a plateau after 120 min. The reason maybe lies in that in
14 short cleavage time, each target only can go through little cycles, so weak signal had
15 been detected. In order to make sure that all DNAzyme/substrate complexes had been
16 cleaved, 120 min had been chosen in this study.

17 18 The preferred position for Fig. 3

19 20 3.3 Calibration curve and reproducibility of the biosensor

21 To estimate the analytical performance of the proposed biosensor, the DPV
22 responses of the system contains different concentration of Pb^{2+} were recorded. As
23 shown in Fig.4A, the DPV response increased gradually with the increasing of Pb^{2+}
24 concentration. This phenomenon is in accord with the fact that higher concentration of
25 Pb^{2+} causing more DNAzyme/substrate complex been cleaved and more eMB
26 produced. The DPV signal has a linear relationship with the Pb^{2+} concentration in the
27 range of 0.05 ~ 1 μM (Fig.4B). The regression equation is:

$$28 \quad \Delta I/\mu\text{A} = 2.5839 * 10^{-2} + 1.1556 * 10^{-1} Cx/\mu\text{M}, R = 0.9960$$

29 Where ΔI (the difference of the currents detected at present and absent of Pb^{2+}) is
30 enhancement of the DPV current, Cx is Pb^{2+} concentration, and R is the regression

1 coefficient. The limit of detection was estimated to be 0.018 μM ($S/N = 3$). This
2 detection limit is more than sufficient for the routine monitoring of lead levels in food
3 and environmental samples required by the U.S. Food and Drug Administration[23].

4 5 **The preferred position for Fig. 4**

6
7 To examine reproducibility of the biosensor, one ITO working electrode was
8 repeatedly used to detect 5 samples (0.6 μM), the relative standard deviation (RSD) is
9 4.13%. And if 5 different ITO working electrodes are used for paralleling
10 determination, the RSD is 4.95% . These results indicate that the proposed method has
11 good repeatability.

12 **3.4 Interference assay and sample determination**

13 The selectivity of the proposed sensor had been studied also. The DPV responses
14 after reaction with Pb^{2+} (1 μM), Cu^{2+} (100 μM), Mn^{2+} (100 μM), Zn^{2+} (100 μM) or
15 Ni^{2+} (100 μM) were shown in Fig.5. The DPV responses in the presence of other
16 divalent metal ions are nearly the same with the blank solution, but remarkable
17 enhancement had been detected in the presence of Pb^{2+} . Therefore, the proposed
18 biosensor has high selectivity to discriminate Pb^{2+} from other.

19 20 **The preferred position for Fig. 5**

21
22 In order to verify the practical application of the proposed method, the lead
23 concentration in simple samples (water samples collected from Minjiang River and
24 lab tap sample) had been detected. The water had been filtered to remove the
25 insoluble substance before determination. It is found that the Pb^{2+} content in the tested
26 sample is too low to be probed by the sensor. However, an obvious increase in readout
27 signal had been observed if different concentrations of Pb^{2+} are added into the sample.
28 So the samples were spiked with Pb^{2+} with the stock solution at the concentration
29 level of 200, 400, 600 nM. Table 1 lists the results obtained using both our sensor and
30 inductively coupled plasma mass spectrometry (ICP-MS). On the basis of an F-test,

1 the results from our present approach are in good agreement with those obtained using
2 ICP-MS. These results reveal the practicality of using our sensor for the determination
3 of Pb^{2+} ions in environmental samples.

5 The preferred position for Table 1

7 4. Conclusion

8 In conclusion, a simple and selective immobilization free solution-phase
9 DNAzyme based electrochemical biosensor for lead determination has been
10 developed. Unlike early reported DNAzyme based electrochemical biosensors which
11 need tedious electrode modification, where the signal probe must be immobilized on
12 the electrode surface, our approach utilized the electrostatic repulsion between DNA
13 probe and the negative ITO working electrode to achieve the immobilization free
14 solution-phase measurement. The mechanism of biosensor was constructed for the
15 detection of DNAzyme cofactor target with decent specificity and sensitivity, which
16 may provide a platform for the fabrication of immobilization free electrochemical
17 sensors for other targets since DNAzymes specific for Cu^{2+} , Zn^{2+} , Co^{2+} have also been
18 obtained.

5 Fig.2 DPV responses of Pb^{2+} (a), MB labeled substrate (b), MB labeled substrate/
6 DNAzyme complex (c) and MB labeled substrate/ DNAzyme complex + Pb^{2+} (d) in
7 Tris-HCl (50 mM, pH 7.4, 10 mM MgCl_2 , 50 mM NaCl) after incubation at 37 °C.
8 [Substrate] = 1 μM , [DNAzyme] = 1.5 μM , [Pb^{2+}] = 1 μM .

9
10 Fig.3(A) Effect of the substrate concentration on the detection system. [DNAzyme] =
11 1.5 μM , [Pb^{2+}] = 1 μM . (B) DPV responses at different cleavage time in Tris-HCl
12 (50 mM, pH 7.4, 10 mM MgCl_2 , 50 mM NaCl) after incubation at 37 °C. [Substrate]
13 = 1 μM , [DNAzyme] = 1.5 μM , [Pb^{2+}] = 1 μM .

14
15 Fig.4(A) DPV responses at different concentrations of Pb^{2+} in Tris-HCl (50 mM, pH
16 7.4, 10 mM MgCl_2 , 50 mM NaCl) after incubation at 37 °C. From a to f: 0 μM , 0.05
17 μM , 0.1 μM , 0.3 μM , 0.6 μM , 1 μM . (B) DPV peak currents plotted against
18 concentration of Pb^{2+} . [Substrate] = 1 μM , [DNAzyme] = 1.5 μM .

19
20 Fig.5 DPV peak currents with various divalent metal ions in Tris-HCl (50 mM, pH 7.4,
21 10 mM MgCl_2 , 50 mM NaCl) after incubation at 37 °C. [Substrate] = 1 μM ,
22 [DNAzyme] = 1.5 μM , [Pb^{2+}] = 1 μM , [the other interferent ios] = 100 μM . Insert: the

1 **Table 1**2 Table 1 Determination of Pb²⁺ in water samples using the proposed method

Sample source	Added /nM	The Proposed Method Mean ± SD/nM (n = 5)	ICP-MS Mean ± SD/nM (n = 5)	F-test between two methods ^a
Tap water	200.0	203.0 ± 2.15	210.7 ± 2.11	1.038
	400.0	413.7 ± 1.61	415.1 ± 1.34	1.444
	600.0	618.1 ± 1.46	613.7 ± 2.21	2.291
River water	200.0	208.1 ± 1.57	211.4 ± 1.69	1.159
	400.0	404.9 ± 2.03	411.5 ± 1.72	1.393
	600.0	615.8 ± 2.18	621.9 ± 3.05	1.957

3 ^a The F-test value is 6.39 at a 95% confidence level.
