This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
Determination of Ultra-trace Cobalt in Water Samples by Graphite Furnace Atomic Absorption Spectrometry after Cloud Point Extraction Using 2-(5-Bromo-2-pyridylazo)-5-dimethylaminoaniline as Chelating Agent

Quan Han*ab, Yanyan Huo, Longhu Yangb, Tiantian Háo, Xiaohui Yanga and Yunhui Zhai

A new method for the determination of ultra-trace cobalt in water sample by graphite furnace atomic absorption spectrometry after cloud point extraction using 2-(5-bromo-2-pyridylazo)-5-dimethylaminoaniline (5-Br-PADMA) as a chelating agent and TritonX-114 as extractant was established. The main parameters affecting extraction, such as pH, concentration, chelating agent and surfactant, equilibrium temperature and time, were investigated in detail. The optimized CPE conditions were as follows: pH=5.5 HAc-NaAc buffer solution, 80 µL 5×10⁻⁴ mol L⁻¹ 5-Br-PADMA, 0.6 mL 1.0 % (w/v) Triton X-114, and heat-assisted at 60℃ for 10 min. Under optimum conditions, the analytical curve was linear in the range of 0.05~1.0 ng/mL and the detection limit was 0.004 ng mL⁻¹ for cobalt, the relative standard deviation was 3.3 % (c=0.5 ng mL⁻¹, n=6), and the recovery were 96.7 %~104.0%. The method was applied to the determination of ultra-trace cobalt in water with satisfactory results.

Introduction

As a component of vitamin B12, cobalt is an essential element with various important physiological functions for human beings, animals, and plants. The deficiency of cobalt in humans and animals usually results in different types of anemia, while excess amounts of cobalt lead to toxic effects. It is clear that the determination of trace amounts of cobalt is important in the field of environmental analysis.

includes: low cost, safety, convenience, simplicity, higher extraction and preconcentration factors.\textsuperscript{11,18} CPE as a preconcentration step in connection with GFAAS for the determination of trace metals have been reported.\textsuperscript{19-25} Yan et al proposed a method for the determination of trace level of cobalt in water sample by GFAAS coupled with CPE using 1-(2-pyridylazo)-2-naphthol (PAN) as a chelating agent and TritonX-100 as extractant. However, the method is rather time-consuming, and it takes 2 h (equilibration time) at 70 °C to complete the quantitative extraction of cobalt.

The purpose of this research paper is to combine CPE with GFAAS and developed a new simple method for the determination of trace cobalt in water samples. In the developed method, 2-(5-bromo-2-pyridylazo)-5-dimethylaminoaniline (5-Br-PADMA)\textsuperscript{26} was chosen as the chelating agent. We chose this particularly because it was a good chromogenic reagent for spectrophotometric determination of cobalt. The structure of the cobalt complex is shown in Scheme 1. In addition, Triton X-114 was used as the extractant because it has a convenient cloud point (in the range of 23-25°C) and a high density of the surfactant-rich phase which facilitates phase separation by centrifugation. The experimental parameters affecting the CPE efficiency were investigated in detail. The proposed method is not only sensitive but also facile, rapid and convenient.

\textbf{Experimental}

\textbf{Apparatus and Reagents}

A model TAS-990 atomic absorption spectrophotometer (Perkin Elmer General Instrument Co. Ltd., Beijing, China) with a deuterium background correction was used for the Co measurements. A cobalt hollow cathode lamp was used as radiation source. The pH values of the solutions were measured by a model PB-10 pH meter (Sartorius Scientific Instrument Co. Ltd., Beijing). A model HH-2 thermostatic bath, maintained at the desired temperature, for cloud point temperature experiments (Kewei Yongxing Instrument Co. LTD., Beijing). A model 800-1 centrifuge (Pudong Physical Instruments Factory, Shanghai, China) was used to accelerate the phase separation. The optimized conditions for GFAAS are given in Table 1.

Double distilled water was used throughout the experimental work. All the chemicals were analytical reagent grade, unless it was stated otherwise. Cobalt standard stock solution: 1000 mg L\textsuperscript{-1} prepared by Co(NO\textsubscript{3})\textsubscript{3}·6H\textsubscript{2}O. Working solutions were obtained by step-wise dilution of this solution. 5×10\textsuperscript{-4} mol L\textsuperscript{-1} 5-Br-PADMA (laboratory-synthesized\textsuperscript{20}) ethanol solution. 1 % (w/v) Triton X-114 (Sigma-Aldrich, Milwaukee, USA) solution. Buffer solution of pH 5.5 was prepared from 0.2 mol L\textsuperscript{-1} HAc and 0.2 mol L\textsuperscript{-1} NaAc solution, correct by pH meter. The 0.1 mol L\textsuperscript{-1} HNO\textsubscript{3}–Methanol solution was prepared by mixing of 0.2
mol L\(^{-1}\) HNO\(_3\) and methanol with equal volume.

**Procedure**

For CPE, an aliquot of working standard cobalt or sample solution, 2.0 mL of acetate buffer solution (pH 5.5), 80 µL of 5.0×10\(^{-4}\) mol L\(^{-1}\) 5-Br-PADMA, 0.6 mL of 1 % (w/v) Triton X-114 were placed in a 10-mL graduated conical centrifuge tube. The mixture was diluted to 10 mL with water. The resultant solution was kept at 60°C for 10 min in the thermostatic bath for equilibration. Following this step, it was then separated into two phases, which was achieved by centrifugation for 5 min at 3500 rpm. After cooling in an ice-bath for 10 min, the surfactant-rich phase became viscous and was retained at the bottom of the tube. The bulk aqueous phase was easily decanted by simply inverting the tube. The surfactant-rich phase was heated in water bath at 100°C to remove the remaining water. 20 µL 0.1 mol L\(^{-1}\) HNO\(_3\)-Methanol solution was added to the remaining phase. The final solution was introduced by conventional aspiration into the furnace for GFAAS determination.

**Results and Discussion**

**Effect of pH**

The chelating agent 5-Br-PADMA exists in the solution in four species H\(_3\)L\(^{3+}\), H\(_2\)L\(^{2+}\), HL\(^+\) and L, with protonation of the ring nitrogen and the two amino group nitrogen atoms. The concentration distribution of the four species is determined by the acidity; therefore, the pH value affects not only the formation, but also the hydrophobicity of the chelate, and is one of the critical parameters. The effect of pH on the extraction of Co was studied within the pH range 3.5-9.0 (Fig.1). As seen in Fig.1, the optimum pH for the extraction of Co is within the range of 5.0 ~ 7.0. In the subsequent experiments, a pH of 5.5 was chosen.

**Effect of the Amount of 5-Br-PADMA**

The effect the amount of 5-Br-PADMA on the analytical responses was studied. As seen in Fig.2, the absorbance increased significantly with the increasing amounts of 5-Br-PADMA, and then kept stable within the range of 60 ~ 100 µL of 5-Br-PADMA. However, the signal decreased gradually when the amount of 5-Br-PADMA was above 100 µL. This was due to the fact that 5-Br-PADMA had strong hydrophobicity. In addition, there was more 5-Br-PADMA and less complex in the surfactant-rich phase with the further increasing of amounts of 5-Br-PADMA. Therefore, 80 µL of 5×10\(^{-4}\) mol L\(^{-1}\) 5-Br-PADMA solution was chosen.

**Effect of the Amount of Triton X-114**

The amount of Triton X-114 affected the extraction efficiency as well as the volume of surfactant-rich phase. The variation in the extraction efficiency affected by the amount of Triton X-114 solution was then investigated. The results are shown in Fig. 3. As can be seen, the absorbance significantly increased with the amount of 1.0 % (w/v) Triton X-114 up to a volume of 0.6 mL, then almost kept stable between 0.6 and 1.2 mL, and finally above 1.2 mL, absorbance decreased. Considering that the increase of the surfactant amount also increased the volume, as well as the viscosity of the surfactant-rich phase obtained after centrifugation of the samples, 0.6 mL of 1.0 % Triton X-114 (w/v) was used in subsequent experiments.

**Effect of the ionic strength**

In cloud point extraction, surfactants with too low or too high cloud points are not convenient and suitable for the separation and preconcentration of trace metals. The appropriate cloud point
temperature avoids back extraction during centrifugation. The cloud point of micellar solutions can be controlled by addition of salts, alcohols, non-ionic surfactants and some organic compounds (salting-out effects). In this study, Triton X-114 was chosen as the extractant due to its convenient cloud point temperature (23-25 °C) as compared to other surfactants and high density of the surfactant-rich phase which facilitates phase separation by centrifugation. The influence of the ionic strength on performance of CPE was investigated in the NaCl concentration range of 0-0.2 mol L⁻¹. The results showed that ionic strength has no significant effect on the extraction efficiency or the sensitivity up to 0.1 mol L⁻¹ NaCl. This is in agreement with the results reported in the literature, which show that an increase in the ionic strength in micelle-mediated systems does not seriously alter the extraction efficiency of the analyte.

**Effect of Equilibration Temperature and Time**

The effect of equilibration temperature and incubation time was investigated. It is desirable to employ the shortest incubation time and the lowest possible equilibration temperature, which compromised completion of the reaction and efficient separation of the phases. The dependence of absorbance upon equilibration temperature and time was studied within the range of 40-80°C and 5-30 min, respectively. The results showed that an equilibrium temperature of 60°C and equilibrium time of 10 min was adequate to achieve quantitative extraction.

**Interferences**

The effect of foreign ions on the determination of 5 ng mL⁻¹ cobalt by the proposed method was studied. An ion was considered to interfere when its presence produced a variation in the absorbance of the sample of more than ±5%. The results showed that 2500-fold amounts of K⁺, Na⁺, Ca²⁺ and Sr²⁺, 2500-fold amounts of Sr²⁺ and Ca²⁺, 2000-fold amounts of Pb²⁺, NO₃⁻, 1000-fold amounts of Mg²⁺, Zn²⁺ and Cu²⁺, 500-fold amounts of Fe³⁺, Al³⁺, F⁻, Br⁻ and I⁻, 400-fold amounts of La³⁺, As(V) and Mo(VI), 200-fold amounts of SO₄²⁻ and Cd²⁺, 100-fold amounts of W(VI), 50-fold amounts of Ce³⁺, Ir⁴⁺ and Mn²⁺, 40-fold amounts of Ag⁺, 20-fold amounts of Pd²⁺, Ce(IV), Bi³⁺, Hg²⁺, and Ni²⁺, and 10-fold amounts of Pt(IV) did not interfere with the measurements.

**Calibration Curve, Detection Limit and Precision**

Under the optimal experimental conditions for preconcentration of cobalt, the calibration graph was linear over the range of 0.05-1.0 ng mL⁻¹ cobalt. The linear equation was \( A=0.06685+0.5344c \), where \( A \) is the absorbance and \( c \) is the cobalt concentration in solution (ng mL⁻¹), and the correlate coefficient was \( R=0.9969 \). The detection limit, calculated as three times the standard deviation of the blank, was 4.0×10⁻³ ng/mL (3\( \sigma \)). The relative standard deviation (RSD) was 3.3% (\( n=11, c=0.2 \) ng·mL⁻¹). In order to determine the preconcentration factor, an analytical curve was prepared without the preconcentration step for cobalt in the range of 20-500 ng mL⁻¹. The calibration equation obtained was \( A=0.0085+1.157×10^{-3}c \). Enrichment factor (EF) calculated as the ratio of the slopes of the calibration graphs obtained with and without preconcentration was 462.

The developed method in this study was compared with the reported methods concerning with cobalt preconcentration by CPE in the existing
literature in terms of detection limits and instruments employed (Table 2). As seen from the table, the detection limit of this method is much better than those given in the table except the literature 25. However, the literature method \textsuperscript{25} is rather time-consuming, and it takes more than 2 h (equilibration time, 2 h at 70℃) to complete the quantitative extraction of cobalt. The this method has comparable detection limit with the literature method,\textsuperscript{25} but it present has a much shorter analytical time, and is facile, rapid and convenient.

| Table 2 | Comparison of the present method with reported methods for the preconcentration and CPE of cobalt |
|---|---|---|---|---|
| Reagent | Surfactant | Technique | DL | Ref. |
| 2-amino-cyclopentene-1-dithiocarboxylic acid | Triton X-114 | SP | 7.5 µg L\textsuperscript{-1} | 31 |

### Determination of Water Samples

Under the recommended experimental conditions, the proposed method was applied to the determination of cobalt in tap and well water samples. In addition, recovery tests were performed, and the results are shown in Table 3. The recoveries are within the range of 96.7 ~ 104 %. These results demonstrated the accuracy and applicability of this method to the analysis of these samples.

| Table 3 | Analytical results of cobalt in water samples and recovery |
|---|---|---|---|---|
| Sample | Added (ng mL\textsuperscript{-1}) | Found (ng mL\textsuperscript{-1}) | Average (ng mL\textsuperscript{-1}) | RSD (%) | Recovery (%) |
| Tap water | 0.30 | 0.288 | 0.272 | 0.275 | 0.280 | 3.2 | 104.0 |

### Conclusion

We have proposed a new method for the determination of cobalt through the combination of CPE with GFAAS using 5-Br-PADAM as chelating reagent and the nonionic surfactant of Triton X-114 as extractant. CPE is a simple, rapid, economical and eco-friendly method for preconcentration and separation of trace metals from aqueous solutions to low volume surfactant-rich phase. GFAAS as a very sensitive spectrometry method is suitable for analysis of low volume of the remained phase after CPE. Triton X-114 was chosen as the extractant due to its convenient cloud point temperature.
(23-25 °C) and high density of the surfactant-rich phase, which separates easily by centrifugation. The results showed that 5-Br-PADMA is a suitable chelating agent for the extraction of cobalt using CPE. The new method gave a highly selective, very sensitive, low cost, and is easily applied to the determination of traces of cobalt in real water samples.
