Accepted Manuscript

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this *Accepted Manuscript* with the edited and formatted *Advance Article* as soon as it is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

17 **Abstract**

18 Nerolidol is a dominant volatile compound isolated from *Oplopanax horridus*.
19 Liquid chromatography-electrospray ionization-mass spectrometry (LC-MS) method
20 was used to evaluate the pharmacokinetics determination of nerolidol in rat. A series
21 of extracting and concentrating methods were optimized for the extraction efficiency
22 of biosamples. Chromatographic separation was performed on a reverse LC column
23 within a total run time of 14.5 min. This method was linear over 10-10,000 ng/mL and
24 the limit of quantification for nerolidol was 10 ng/mL, with both inter-day and
25 intra-day (CV) precision < 8% and accuracy (RE) ranged from -6% to 6%. Stabilizing
26 determination of the plasma concentration of nerolidol was supported over a period of
27 27 h.

30 **Keywords:** nerolidol, pharmacokinetics, LC-MS, extraction optimization

31 **Abbreviations used:** IS, internal standard; IP, intraperitoneal; AUC, area under curve;
32 C_{\max} , area maximum concentration; T_{\max} , time to maximum concentration; $T_{1/2}$,
33 elimination half-life; MRT, mean residence time; Cl/F, clearance.

35 Introduction

36 *Oplopanax horridus*, commonly known as Devil's club, has been used in folk
37 medicine by the native tribes of Alaska and Northwest China for centuries[1].
38 Traditionally, the inner bark of roots and stems were applied to medical usage[2].
39 Nerolidol, a natural aliphatic sesquiterpene alcohol, is the major sesquiterpene
40 constituent extracted from stems and roots of *Oplopanax horridus*[3]. It also could
41 be extracted from various plants and used in many fragrance compounds as a
42 fragrance ingredient and flavor[4]. Moreover, nerolidol has exhibited plenty of
43 medicinal benefits such as antioxidant activity, antibacterial properties, antitumor
44 effects, antiulcer functions, and inhibiting the growth of parasite[5-9]. However,
45 apart from these pharmacological studies, there is only one newly published paper
46 reported an in-vivo analysis of nerolidol in mice by GC/MS method[14].
47 Meanwhile, the stability of samples and the extraction method did not investigated
48 in this published paper[14]. As LC/MS is also a sensitive and widely used method,
49 in this study, a valid and efficient LC/MS method was developed for determination
50 of nerolidol in rat plasma. After that, this method was successfully applied to
51 investigate the *in vivo* pharmacokinetics of nerolidol in rats.

53 Experimental

54 Chemicals, material and reagents

55 Nerolidol (*cis/trans* : 40/60) and Tween 80 were obtained from Sigma-Aldrich
56 Inc. (St Louis, MO, USA). Diazepam was obtained from National Institute for the
57 Control of Pharmaceutical & Biological Products (NICPBP, Beijing, China).
58 Methanol and formic acid (HPLC grade) were obtained from ROE Scientific Inc.
59 (Newcastle, PA, USA). Purified water prepared by the Millipore system (Millipore,
60 Bedford, MA, USA) was employed for all the preparations. Other reagents were of
61 analytical grade and purchased from Jiangsu Hanbon Sci. & Tech. Co. Ltd (Nanjing,
62 Jiangsu, China).

63 Equipment and LC/MS condition

64 An Agilent 1100 series LC system (Agilent Technologies, Palo Alto, CA, USA)
65 equipped with a dual pump and a Rheodyne7125i injection valve with a 20 μ L sample
66 loop was employed to performance the chromatographic analysis. Data were acquired
67 and processed by a HP ChemStation. Chromatographic separation was performed
68 with a Thermo Hypersil BDS C18 column (4.6 mm \times 255 mm i.d., 5 μ m) with an
69 Agilent ZORBAX ODS C18 as the guard column (4.6 mm \times 12.5 mm i.d., 5 μ m).
70 Throughout the procedure, columns were maintained at room temperature. The
71 mobile phase consisted of (A) 0.1% aqueous formic acid and (B) methanol. The
72 isocratic elution condition was 80% B (A : B, v / v) kept for 14.5 min. The injection
73 volume was 5 μ L and the flow rate was 1 mL/min.

74 An Agilent MSD SL-G2710BA with an electrospray ionization source (Agilent
75 Corp, Santa Clara, CA, USA) was employed to perform detection by monitoring the
76 ions. The analysis parameters were as follows: fragmentor voltage, 120 V; drying gas
77 (N_2) flow rate, 10 L/min; gas temperature, 320 $^{\circ}$ C; nebulizer gas (N_2) pressure, 40
78 psig; capillary voltage, 3500 V. Analysis for diazepam and nerolidol was done in a
79 positive ion mode with single ion monitoring (SIM) m/z values restricted to specific
80 retention time windows 0-7.5 min, m/z 285.00 [M + H] $^{+}$; 7.5-14.5 min, m/z 205.00
81 [M - H $_2$ O + H] $^{+}$.

82 Preparation of standard solutions and quality control samples

83 The stock solution of nerolidol was prepared in mobile phase solution at the
84 concentration of 100 μ g/mL, while the stock solution of internal standard (diazepam)
85 was prepared in methanol at the concentration of 1 μ g/mL. All solutions were kept in
86 volumetric flasks at 4 $^{\circ}$ C before subsequent analysis.

87 Quality control (QC) samples were prepared in blank rat plasma by spiking
88 appropriate aliquots from the stock solutions to obtain final concentrations at 20
89 ng/mL (low), 2,000 ng/mL (medium) and 10,000 ng/mL (high), respectively. All the
90 spiked plasma samples were then processed according to optimized biosample
91 preparation procedure.

92

93 Biosample preparation

94 Each 0.1 mL of plasma spiked with 0.01 mL of internal standard (IS: diazepam)
95 solution was combined with 1.0 mL of precooled ethyl acetate/n-butyl alcohol ($v: v =$
96 90: 10) in a centrifuge tube. Then the solution was vortex-mixed for 1 min and
97 centrifuged at 13,000 rpm for 10 min at 4 °C. The supernatant was transferred to
98 another tube. This process was repeated once again and the supernatants were
99 combined and dried by an EZ-2 evaporator with precise temperature control (Genevac
100 Inc., Suffolk, UK) in very low BP mode. The dried residue was reconstituted in 100
101 μ L mobile phase solution and then centrifuged. The supernatant was used for analysis.
102 All the preparation was conducted within ice-bath and all tubes were wrapped with
103 tinfoil in order to keep the samples at relatively low temperature and away from light.

104 Method validation**105 Linearity, accuracy, precision and lower limit of quantification**

106 Linearity was evaluated by developing and assaying plasma calibration curves
107 from 10-10,000 ng/mL, respectively. Plasma samples were quantified through the
108 ratio of the sum peak area of *cis*-nerolidol and *trans*-nerolidol to that of IS. A linear
109 regression function after $1/x^2$ weighting of the nerolidol/IS peak area ratio versus
110 nerolidol concentration relationship was established. Intra-day and inter-day accuracy
111 and precision were determined by assaying QC sample at three concentration levels.
112 Accuracy was calculated as percent deviation from the nominal concentration (RE)
113 while precision was determined by the coefficient of variation (CV). The lower limit
114 of quantification (LLOQ) was determined as the lowest concentration with a
115 signal-to-noise (S/N) ratio of 10, and both the precision and accuracy less than 20%
116 by analyzing six replicates of analyte.

117 Recovery and matrix effect

118 The recoveries of nerolidol at three QC levels ($n= 5$) were determined by
119 comparing the responses of the analytes from QC samples with the responses of
120 analytes spiked in post-extracted samples at equivalent concentrations. Matrix effects

1
2
3
4 121 on the ionization of nerolidol were evaluated by comparing the responses of analytes
5
6 122 added into pre-extracted plasma from untreated rats with those of analytes dissolved
7
8 123 in the same volume of initial mobile phase.

9 124 **Stability**

10
11 125 QC samples at three concentrations stored at -80 °C were analyzed to evaluate
12
13 126 the stability of analytes. Two freeze-thaw cycles of the QC samples were performed at
14
15 127 4 and 27 h ($n = 5$). Stock solution and post-preparative stability were tested at 24 h (n
16
17 128 = 5).

18 129 **Animal experiment**

19
20 130 Normal male Sprague-Dawley rats weighing 250-300 g were obtained from
21
22 131 BiKai Co., Ltd. (Shanghai, China) and kept at 25 ± 2 °C and $65 \pm 5\%$ relative
23
24 132 humidity on a 12 h light-12 h dark cycle. All animals had free access to food and
25
26 133 water until 12 h prior to the experiment. All animal experimental procedures were in
27
28 134 accordance with protocols that approved by the Review Committee of Animal care
29
30 135 and Use of China Pharmaceutical University.

31
32 136 To obtain stabilized drug solution, nerolidol was mixed with a pre-heated
33
34 137 medium containing Tween 80, ethanol (nerolidol: Tween: ethanol = 1 : 2 : 2). After
35
36 138 vortex-mixed for 0.5 min, the medium containing nerolidol was dissolved in the
37
38 139 physiological saline solution to obtain the final solvent containing 90% saline, 0.5%
39
40 140 Tween 80 and 0.5% ethanol. After two weeks' accommodation, the rats were fasted
41
42 141 for 12 h before the experiment. Nerolidol (25 mg/kg; *cis/trans*: 40/60) was
43
44 142 administered by intraperitoneal (IP) injection. Under light ether anaesthesia, blood
45
46 143 samples were collected from retinal venous plexus into heparinized tubes at time
47
48 144 points 0, 5, 10, 20, 30, 60, 90, 120, 240 and 360 min after dosing. The samples were
49
50 145 immediately centrifuged at 13,000 rpm for 10 min at 4 °C. The plasma was finally
51
52 146 obtained and stored at -80 °C until analysis.

53
54 147 Plasma concentration-time data were analyzed by Drug and Statistics 2.0 (DAS
55
56 148 2.0) software package (Mathematical Pharmacology Professional Committee of China,
57
58
59
60

1
2
3 149 Shanghai, China) to obtain pharmacokinetic parameters.
4
5
6 150

7 151 **Results and Discussion**

9 152 **Quantitation target**

11 153 Considering that little evidence could support the single isomer's bioactivity or
12 154 toxicity because they were often administrated as a whole (*cis/trans* = 40/60) [10].
13
14 155 Therefore, we temporarily established a valid method to determine the
15
16 156 pharmacokinetics of total *cis-trans* isomers of nerolidol due to the undisputable
17
18 157 bioactivity of the total nerolidol isomers according to a series of preclinical and
19
20 158 clinical study[11, 12].
21
22

23 159 **Optimization of biosample preparation**

25 160 During the development of preparation method, different extraction approaches
26
27 161 including protein precipitation, SPE and liquid-liquid extraction were investigated.
28
29 162 Though protein precipitation is relatively simple, the recoveries for nerolidol were
30
31 163 low either using methanol or acetonitrile as protein precipitation agents. SPE is a
32
33 164 common technique for sample preparation as it often offers higher sensitivities.
34
35 165 However, the recoveries for nerolidol were not satisfactory. Alternatively,
36
37 166 liquid-liquid extraction was used. Several extraction solvent such as ethyl acetate,
38
39 167 ethyl acetate/n-butyl alcohol ($v: v = 95 : 5$), ethyl acetate/n-butyl alcohol ($v: v = 90 :$
40
41 168 10), ethyl acetate/n-hexane ($v: v = 95 : 5$), ethyl acetate/n-hexane ($v: v = 90 : 10$) were
42
43 169 tested, after which ethyl acetate/ n-butyl alcohol ($v: v = 90 : 10$) was selected as
44
45 170 extraction solvent because of its high extract efficiency. Considering the instability
46
47 171 and volatility of nerolidol, two comparative concentrating approaches including
48
49 172 pressured nitrogen blowing concentration and EZ-2 evaporator under controlled low
50
51 173 temperature were tested to optimize the concentration process. As shown in Table 1,
52
53 174 the EZ-2 evaporator exhibited better recovery efficiencies. Thus, ethyl acetate/ n-butyl
54
55 175 alcohol ($v: v = 90 : 10$) extraction system and evaporator station were the final
56
57 176 optimized method for biosample extraction.
58
59
60

Method validation

The approximate retention times for internal standard (IS), *cis*-nerolidol and *trans*-nerolidol (Figure1) were 5.1 min, 11.9 min and 13.1 min (Figure1), respectively. No interfering peak from endogenous substances was observed at the times of the analyte and IS, suggesting a good selectivity of the developed method.

The linear regression of nerolidol in the plasma of rats demonstrated good linear relationships over the range from 10 to 10,000 ng/mL. The regression equation of the calibration curve for nerolidol in the plasma was: $y = 0.9081x + 0.0266$ ($r^2 = 0.9985$).

As shown in Table 2, both inter-day and intra-day precision of all the QC samples were within the acceptable range (< 8%) and accuracy (% bias) ranged from -6% to 6%. The LLOQ was 10 ng/mL, suggesting this method is sensitive.

As shown in Table 3, the extraction recoveries at three concentration levels of the analyte were all within the acceptable limit (~ 90%). Moderate matrix effects (< 10%) as shown in Table 2, indicated no significant interference from endogenous compounds occurred. The stability of the nerolidol could be affected by many enzymes in the biological matrix and the ambient temperature. As presented in Table 4, QC samples were found to be stable in the plasma through two freeze-thaw cycles. Relative errors (RE) for nerolidol were lower than 11% after 4 h and 16% after 27 h freeze-thaw cycles, indicating approved stability for subsequent study conditions. For stability of stock solution and post-preparative solution, RE were both lower than 4% after 24 h.

Pharmacokinetics analysis

The highest nerolidol level was observed in the plasma at 20 min after single intraperitoneal injection. The peak plasma concentration (C_{max}) for the nerolidol was 8.30 ± 1.07 (mean \pm S.E.) mg/L. The area under the concentration curves (AUC) was 307.81 ± 42.90 mg•min/L. The corresponding pharmacokinetic parameters including the mean residence time (MRT), elimination half-life ($T_{1/2}$) and clearance (Cl/F), were summarized in Table 5. The plasma concentration-time curve after a single

1
2
3 205 intraperitoneal injection of nerolidol of was shown in Figure 2.
4
5 206

7
8 207 **Discussion**

9
10 208 Nowadays essential oils are not only used as phytotherapy treatments, but also
11 209 extensively used in decorative cosmetics, toilet products and detergents. However,
12 210 little information about *in vivo* pharmacokinetics of essential oils or their constituents
13 211 are available.

14 212 Usually gas chromatography was adopted as the analysis method of essential oil
15 213 in *Oplopanax horridus* [13]. Recently, a newly published paper reported an *in-vivo*
16 214 analysis of nerolidol in mice by GC/MS method [14]. The report validated the
17 215 adopted method, and for the first time conducted the quantitation of nerolidol *in-vivo*.
18 216 However, this report did not investigate the stability of sample and extraction
19 217 methods , nor did it resolve the quantitation of single isomer of neroliodol. As
20 218 essential oil including nerolidol often exhibits instability and was formidable to
21 219 extract from biosample, LC/MS, with convenience and stability features, could also
22 220 be taken into account to evaluate the *in vivo* pharmacokinetics of nerolidol. Moreover,
23 221 there were several researches on the LC analysis of essential oil, and they manifested
24 222 valid and stable quantitation avenues towards those instable compounds[15].

25 223 In this study, some distinct yet a series of frequently-used extraction and
26 224 concentration method were tested. Based on the extraction efficiency, we obtain the
27 225 best extraction condition which could benefit the subsequent LC/MS analysis.
28 226 Furthermore, compared with the previous GC-MS method, the matrix effect is greatly
29 227 improved in our studies. In addition, samples were found to be stable in the plasma
30 228 through two freeze-thaw cycles. Thus we could determine the pharmacokinetics
31 229 parameters on the basis of relatively high and stable extraction efficiency of nerolidol.
32 230 Further, this combinatorial optimized method could be developed as a general
33 231 reference for the *in-vivo* volatile compound analysis.

34 232 However, there is an inevitable question that the compound has *cis-trans*

1
2
3 233 isomerism (*cis/trans* = 40/60). In this study, we have merely determined the total
4
5 234 pharmacokinetic parameters of the isomers instead of each and every single isomer.
6
7 235 The major concern was that there was little evidence to support the single isomer's
8
9 236 bioactivity or toxicity because they were often administrated as a whole [11,16].
10
11 237 Therefore, we temporarily established a valid method to determine the
12
13 238 pharmacokinetics of total *cis-trans* isomers of nerolidol. There was a report using LC
14
15 239 method to separate essential oils in Devil's Club. Compared to this report, we
16
17 240 optimized mobile phase and elution speed in order to provide a distinct separation
18
19 241 between *cis* and *trans* nerolidol. Despite we have not quantitate single isomer of
20
21 242 nerolidol, the distinct separation of isomers could reveal the compound profile and
22
23 243 provide analysis regime for further analysis if stable standard isomer is available.
24
25 244 Further research was needed, if necessary, to confirm the pharmacokinetics of each
26
27 245 specific isomer.
28

29 246

30 31 247 **Conclusion**

32
33 248 In this project, we studied the *in vivo* pharmacokinetics of nerolidol in rats. The
34
35 249 extraction and concentration methods were optimized in order to minimize the
36
37 250 decomposition effect and avoid other factors that would impact the nerolidol
38
39 251 extraction efficiency. An optimized method for extracted nerolidol from biosample
40
41 252 and a sensitive, accurate and reproducible LC-MS method were developed and
42
43 253 validated for the quantification of nerolidol. Moreover, because of its broad
44
45 254 distribution in herbal products, our results could provide some suggestion in regards
46
47 255 to the dose safety and regime of nerolidol during further clinical administration or
48
49 256 civil employment of this perspective compound.

323 **Table 1**

324 Comparison of extraction efficiencies of nerolidol in plasma by SPE, liquid-liquid
 325 extraction and protein and concentration approaches under the optimal conditions
 326 (mean \pm S.D., $n = 6$).

Extraction Method	Theoretical (ng/mL)	Observed (ng/mL)	CV (100%)
Solid Phase Extraction			
C18 packing (water/methanol)	1,000	367 \pm 34	9.16
C18 packing (water/acetonitrile)	1,000	505 \pm 69	13.69
HLB packing (water/methanol)	1,000	497 \pm 43	8.70
HLB packing (water/acetonitrile)	1,000	618 \pm 30	4.84
Liquid-Liquid Extraction			
ethyl acetate	1,000	706 \pm 52	7.39
ethyl acetate/n-butyl alcohol (v: v = 95:5)	1,000	741 \pm 20	2.73
ethyl acetate/n-butyl alcohol (v: v = 90:10)	1,000	809 \pm 33	4.14
ethyl acetate/n-hexane (v: v = 95:5)	1,000	646 \pm 49	7.53
ethyl acetate/n-hexane (v: v = 90:10)	1,000	627 \pm 34	5.41
Protein Precipitation			
methanol	1,000	315 \pm 58	18.30
acetonitrile	1,000	297 \pm 63	21.12
Concentration Method	Theoretical (ng/ml)	Observed (ng/mL)	CV (100%)
Nitrogen Concentration			
EZ-2 evaporator	1,000	924 \pm 19	3.14

333

334 **Table 2**

335 Method validation for nerolidol in rat plasma (accuracy and precision)

Inter-day	Theoretical (ng/mL)	Observed (ng/mL)	CV(100%)	RE(100%)
	10	9.48 ± 0.7	7.47	-5.20
	20	19.8 ± 1.1	5.18	-1.24
	2,000	2083 ± 109	5.26	4.20
	10,000	9,992 ± 657	4.58	-1.08
Intra-day	Theoretical (ng/mL)	Observed (ng/mL)	CV(100%)	RE(100%)
	10	10.4 ± 0.6	7.05	5.63
	20	20.7 ± 1.2	5.73	3.70
	2,000	2,116 ± 142	6.69	5.84
	10,000	10,182 ± 701	5.89	2.87

336 Concentrations measured are reported as mean ± SD; $n = 5$ for both inter-day and

337 intra-day determination.

346 **Table 3**

347 Extraction efficiency and matrix effect for nerolidol in rat plasma

Added (ng/mL)	Extraction Efficiency (% mean, <i>n</i> = 5)	Matrix Efficiency (% mean, <i>n</i> = 5)
20	88.81 ± 2.75	5.86 ± 0.45
2,000	90.58 ± 1.50	9.19 ± 1.14
10,000	91.61 ± 1.71	8.62 ± 3.35

348 Concentrations measured are reported as mean ± SD; *n* = 5 for both Extraction efficiency

349 and Matrix efficiency determination.

366

367 **Table 4**
368 Short-Term Temperature Stability, Long-Term Stability, Stock Solution Stability and
369 Post-Preparative Stability

Added (ng/mL)	RE% (4 h)	RE% (27 h)
20	-2.22	-8.67
2,000	-6.57	-9.18
10,000	-10.92	-15.78

Concentration (ng/mL)	RE% (Stock solution)	RE% (Post-preparative solution)
100,000	-2.10	-3.47

370 Concentrations measured are reported as mean \pm SD; $n = 5$ for both Extraction efficiency

371 and Matrix efficiency determination.

372

373 **Table 5**

374 Mean pharmacokinetic parameters of nerolidol in rat serum (n = 5) after
 375 administration nerolidol (25 mg/kg, ip).

PK Parameters	Nerolidol
AUC (mg•min/L)	307.81 ± 42.90
MRT (min)	27.72 ± 2.14
$T_{1/2}$ (min)	20.98 ± 7.71
Cl/F (L/min/kg)	0.082 ± 0.012
T_{max} (min)	20
C_{max} (mg/L)	8.30 ± 1.07

376 Data expressed as mean ± S.E. (n = 5). AUC: area under the concentration vs. time
 377 curve; MRT: mean residence time; $T_{1/2}$: elimination half-life; Cl/F: clearance; T_{max} :
 378 time point of maximum blood concentration of drug; C_{max} : maximum concentration.
