Accepted Manuscript

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this *Accepted Manuscript* with the edited and formatted *Advance Article* as soon as it is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

4 Dezhao Kong, Liqiang Liu, Shanshan Song, Hua Kuang, Chuanlai Xu*

5
6 An immunochromatographic strip was developed for the semi-quantitative and
7 quantitative detection of biotin in milk and milk products. This detection system was
8 developed based on a sensitive and specific monoclonal antibody produced in our
9 laboratory. The semi-quantitative results, which were visually obtained in 20 min,
10 revealed that the visual limit of detection was 2.0 $\mu\text{g}/100\text{ g}$ with a cut-off value of 8.0
11 $\mu\text{g}/100\text{ g}$. The quantitative results, which are obtained with a strip scan reader,
12 revealed that the calculated limit of detection was 0.32 $\mu\text{g}/100\text{ g}$ with a linear range of
13 0.65–68 $\mu\text{g}/100\text{ g}$. Biotin content in milk and milk products were determined by the
14 developed immunochromatographic strip, and the results were validated by the
15 microbiological assay method. Our developed immunochromatographic strip system
16 is suitable for the on-site detection and rapid screening of biotin in food samples.

1 Introduction

2 Biotin (coenzyme R, D-biotin, vitamin B7, vitamin H, and W factor),¹ is a
3 water-soluble B vitamin, which participates in multiple metabolic reactions and
4 affects growth and development in living organisms.²⁻⁵ Biotin cannot be synthesized
5 by humans and other mammals; therefore, the vitamin must be obtained from dietary
6 sources such as egg yolk, organ meats, vegetables, and dairy products. Additionally,
7 bacteria present in the large intestine synthesize the vitamin.⁶⁻⁸ Biotin deficiency,
8 while rare, occurs in subjects with inborn lack of biotin bio-enzyme,^{9,10} on long-term
9 therapy with anticonvulsant agents¹¹ or parenteral nutrition,^{12,13} with inflammatory
10 bowel disease,^{14,15} or with alcohol addiction^{16,17}. Biotin deficiency causes xerosis
11 cutis, erythra, and hair mats. Based on animal studies, biotin deficiency during
12 pregnancy leads to embryonic growth retardation, congenital malformation, and
13 death.¹⁸⁻²¹ In infants, biotin deficiency leads to severe neurological symptoms and
14 sudden infant death syndrome. Therefore, biotin was supplied in many kinds of food,
15 especially the infant foods or some related dietary supplements.²²⁻²⁵ Biotin
16 determination in fortified or enriched foods such as dietary supplement and infant
17 formula is an important aspect of the food industry.

18 Currently, biotin can be determined by instrument detection methods²⁶⁻²⁹ or
19 microbiological assays.³⁰⁻³³ While the instrument detection methods are sensitive and
20 accurate, they are expensive, time consuming, and require complex sample
21 pretreatment steps. The microbiological assay, which is the most sensitive, is the
22 standard biotin determination method worldwide. The VitaFast® Vitamin B7 Biotin
23 kit, developed by R-Biopharm Co., Ltd. (Germany), is a microbiological assay with a

1
2
3 1 detection range of 0.08–0.72 µg biotin/100 g (ml). However, the instability and high
4
5 2 price of the test kit limit its applications.
6

7 3 The enzyme-linked immunosorbent assay (ELISA), which is simple, inexpensive,
8
9 4 and sensitive, is based on antigen-antibody reactions and is an ideal method for the
10
11 5 rapid determination of biotin in food samples.³⁴ Biotin–Streptavidin System is a
12
13 6 newly biological response amplifying system. And this system also be used for the
14
15 7 detection of biotin.³⁵ Additionally, the lateral-flow immunochromatographic strip
16
17 8 assay represents a rapid, simple, inexpensive, and instrument-free diagnostic tool^{36,37}.
18
19 9 In the immunochromatographic strip assay, semi-quantitative results can be obtained
20
21 10 in 5–10 min,³⁸ while quantitative results can be rapidly obtained with strip scan
22
23 11 readers.^{39,40} In this study, we developed and optimized an immunochromatographic
24
25 12 strip for the semi-quantitative and quantitative determination of biotin in milk and
26
27 13 milk products.
28
29

31
32
33

34 **Materials and methods**

36 **Chemicals**

37
38
39 17 Biotin N-hydroxysuccinimide ester (Biotin-NHS) and bovine serum albumin (BSA)
40
41 18 were obtained from Sigma (St. Louis, MO, USA). Goat anti-mouse immunoglobulin
42
43 19 (IgG) antibody was purchased from Jackson ImmunoResearch Laboratories. Other
44
45 20 reagents and chemicals were acquired from the National Pharmaceutical Group
46
47 21 Chemical Reagent Co., Ltd. (Shanghai, China).
48
49

50 22 Nitrocellulose (NC) high-flow-plus membrane (Pura-bind RP) was obtained from
51
52 23 Whatman-Xinhua Filter Paper Co. (Hangzhou, China). Sample pad (CB-SB08),
53
54 24 polyvinylchloride (PVC) backing card, and absorption pad (SX18) were supplied by
55
56 25 Goldbio Tech Co. (Shanghai, China). Conjugated coating antigens (Biotin-BSA) and
57
58
59
60

1 specific monoclonal antibodies (anti-Biotin mAb, No. 3C2) were generated in our
2 laboratory.

3 All buffer solutions were prepared with ultrapure water (Milli-Q purification
4 system, Millipore Co., Bedford, MA, USA). AirJet Quanti 3000TM and BioJet Quanti
5 3000TM were used as dispensers (XinqidianGene-technology Co. Ltd., Beijing, China),
6 and the strip cutting instrument was CM 4000 (Gene, Shanghai, China). The strip scan
7 reader was provided by Huaan Magnech Bio-Tech Co., Ltd. (Beijing, China).

9 **Preparation of coating antigen and anti-biotin mAb**

10 For the preparation of the immunochromatographic strip, biotin-BSA coating antigen
11 was synthesized in our laboratory. Biotin-NHS was conjugated with BSA by the
12 active ester method. BSA was dissolved in 0.1 M sodium carbonate-bicarbonate
13 buffer (CB, pH 9.6) at 10 mg/ml, and biotin-NHS was dissolved in N, N-dimethyl
14 formamide at 5 mg/ml. First, biotin-NHS was added dropwise into 1 ml BSA, and the
15 mixture was stirred at room temperature (RT) for 2 h. The pH value was adjusted to
16 7.4. Subsequently, 20 μ l of 2 M NH₄Cl was added to the solution and stirred at RT for
17 10 min. The conjugates were dialyzed against 0.01 M phosphate buffer solution (PBS)
18 for 3 d and subsequently against distilled water for 3 d.

19 The anti-biotin mAbs were synthesized in our laboratory and purified from ascites via
20 the caprylic acid-ammonium sulfate precipitation method. Indirect competitive ELISA
21 (ic-ELISA) was used for the characterization of mAb which was similar to
22 conventional protocols.^{41,42} The 96-well microwell plates were coated (100 μ L/well)
23 with coating antigen at 37°C for 2 h, washed, and blocked with 2% gelatin in CB at
24 37°C for 2 h. After washing, 50 μ L anti-biotin mAb and 50 μ L analytes at different
25 concentrations in 0.01 M PBS were added to each well, followed by incubation at
26 37°C for 30 min. Next, 50 μ L horseradish peroxidase (HRP)-labelled goat

1 anti-mouse IgG was added to each well and incubated at 37°C for 30 min. After three
2 washes, 100 µL 3, 3', 5, 5'-tetramethylbenzidine (TMB) substrate was added and
3 incubated at 37°C for 15 min. The enzymatic reaction was terminated with 50 µL
4 sulfuric acid (2 M) per well, and the results read using the microplate reader at 450
5 nm.

6 The limit of detection (LOD) and 50% inhibition concentration (IC₅₀) values were
7 determined by a standard curve generated by plotting B/B₀ values (where B represents
8 the absorbance at each concentration of biotin and B₀ represents the absorbance in the
9 absence of biotin) on the y axis against biotin concentration on the x axis. The mAb
10 specificity was determined by cross-reactivity (CR):

$$11 \quad CR (\%) = (IC_{50} \text{ of biotin} / IC_{50} \text{ of competition analogue}) \times 100\%^{43}$$

13 **Labelling of the mAb with gold nanoparticles (GNPs)**

14 Gold nanoparticles (GNPs) preparation and labelling experiment in our laboratory
15 was as previously described.⁴⁴⁻⁴⁶ The pH value of the GNP solution was adjusted with
16 0.1 M K₂CO₃. Purified mAb dissolved in 200 µl of 0.01 M PBS was added dropwise,
17 and the mixture was incubated at RT for 1 h. During this incubation period, mAbs
18 form complexes with GNPs via electrostatic interactions. Subsequently, 1 ml of 0.5%
19 BSA (w/v) dissolved in 0.01 M PBS was slowly added dropwise into the mixture
20 solution, and then incubated at RT for 2 h. BSA was used to block the GNPs and to
21 stabilize the labeled mAb. The solution was centrifuged twice at 7,000 g and washed
22 with 0.02 M PBS (containing 5% sucrose, 1% BSA, and 0.5% PEG 6000, pH 7.4).
23 The resulting precipitate of GNP-labelled mAbs was dissolved in 1 ml gold-labelled
24 re-suspension buffer⁴⁷ (0.02 M PBS, 5% sucrose, 1% BSA, 0.02% NaN₃) and stored
25 at 4°C.

26

1 **Preparation of the immunochromatographic strip**

2 The immunochromatographic strip consisted of four parts: a sample pad, an NC
3 membrane, a PVC backing card, and an absorption pad (Figure 1A). The NC
4 membrane was attached to the middle of the PVC backing card; the sample and
5 absorption pads were attached on both ends of the PVC backing card with a 2-mm
6 overlap in the NC membrane. The sample pad was first immersed in 0.01 M PBS
7 (containing 1% BSA and 0.2% Tween-20) and dried at RT for 4 h to minimize
8 nonspecific binding and matrix interference.⁴⁸ Goat anti-mouse IgG was sprayed onto
9 the NC membrane at 1 $\mu\text{l}/\text{cm}$ with a membrane dispenser (Xinqidian
10 Gene-Technology Co. Ltd., Beijing, China), resulting in the formation of the control
11 line (C line). The coating antigen was sprayed onto the NC membrane at 1 $\mu\text{l}/\text{cm}$,
12 resulting in the formation of the test line (T line). The NC membrane was dried at
13 37°C for 30 min. The prepared strip card was cutting onto individual test strips by the
14 cutting instrument (CM 4000) with the width at 3 mm and then stored in a desiccator
15 for further test.

16 **Principle of the immunochromatographic strip assay**

17 Prior to the test, 150 μl of sample solution was mixed with 50 μl of GNP-labelled
18 mAb, allowed to react at RT for 5 min, and added to the sample pad. The solution on
19 the sample pad migrated towards the absorbent pad. The test results were visually
20 obtained in 5 min.

21 In biotin-negative samples, GNP-labelled mAbs either form a complex with the
22 coating antigens on the T line or are captured by the goat anti-mouse IgG antibodies
23 on the C line (Figure 1B). Therefore, in biotin-negative samples, two red lines emerge
24 on the strip. In biotin-positive samples, GNP-labelled mAbs conjugate with biotin in
25

1
2
3 1 the sample solution, limiting the amount of GNP-labelled mAbs that could bind to the
4
5 2 coating antigens. Both free GNP-labelled mAbs and GNP-labelled mAbs conjugated
6
7 3 with biotin are captured by the goat anti-mouse IgG antibodies on the C line.
8
9 4 Therefore, in biotin-positive samples, the T line has a weaker color intensity than in
10
11 5 biotin-negative samples, while the C line color intensity is similar between positive
12
13 6 and negative samples. Consequently, the color intensity of the T line is inversely
14
15 7 proportional to the concentration of biotin in the sample. The C line should always
16
17 8 emerge; otherwise, the procedure was incorrectly performed or the strip was poorly
18
19 9 assembled.⁴⁹
20
21
22
23
24

25 11 **Characterization of the immunochromatographic strip**

26
27 12 The sensitivity of the immunochromatographic strip was determined using a series of
28
29 13 samples containing different concentrations of biotin.
30
31

32 14 For the semi-quantitative assay, results were obtained with the naked eye. The
33
34 15 visual limit of detection (vLOD) value was defined as the lowest concentration of
35
36 16 biotin that resulted in a definitely weaker T line color intensity than that of the C line
37
38 17 color intensity. The cut-off value was the threshold of biotin concentration that
39
40 18 resulted in the disappearance of the T line.
41
42

43 19 For the quantitative assay, the color intensity of the T line was determined with a
44
45 20 handheld strip scan reader. T/T_0 values on the y axis (where T represents the optical
46
47 21 density value of the T line with the positive sample and T_0 represents the optical
48
49 22 density value of the negative sample) were plotted against biotin concentration on the
50
51 23 x axis. The calculated limit of detection (cLOD) was defined as the concentration with
52
53 24 10% inhibition of the signal (IC_{10}).
54
55
56
57
58
59
60

1 Sample analysis for the immunochromatographic strip assay

2 Different types of milk and milk products were used for the validation of the
3 developed immunochromatographic strip. Raw milk was obtained from Talent dairy
4 beverage factory (Wuxi, China). Pure milk, infant milk powder, and instant whole
5 cream milk powder were obtained from a local market. The content of biotin in the
6 samples was confirmed by the microbiological assay against the national food safety
7 standard GB 5413.19-2010. In national standard GB 5413.19-2010, the sample was
8 mix with culture medium without biotin and then inoculate with the tested bacterial
9 strain *Lactobacillus plantarum*, ATCC 8014. The growth of microorganisms has a
10 linear relation with the content of target material. Then the content in sample could be
11 calculated based on the absorbance comparative between sample and standard curve.

12 Raw milk samples (R1, R2, R3, and R4) and pure milk samples (P1, P2, P3, and
13 P4) were centrifuged at 5,000 g for 15 min at 4°C. Following the removal of the lipid
14 layer, the skim milk samples were analyzed by the immunochromatographic strip
15 assay. One gram of infant milk powder samples (I1, I2, I3, and I4) and one gram of
16 instant whole cream milk powder (M1, M2, M3, and M4) were heat-dissolved in 9 ml
17 aqua pura (30 min at 50°C), allowed to cool, and centrifuged at 5,000 g for 15 min at
18 4°C. The lipid layer was removed, and the skim milk samples were analyzed by the
19 immunochromatographic strip assay.

20 Results and Discussion

21 Characterization of coating antigen and mAb

22 The coating antigens were synthesized in our laboratory. Biotin-NHS was conjugated
23 to BSA at different ratios (BSA:Biotin-NHS; 1:2, 1:4, and 1:8 M:M), and the coating
24 antigens were characterized by sodium dodecyl sulfate polyacrylamide gel
25

1
2
3 1 electrophoresis (SDS-PAGE; Figure 2A). The molecular weight (MW) of coating
4
5 2 antigens (Biotin-BSA conjugates) were greater than the BSA. Under the SDS-PAGE
6
7 3 method, the migration rate of coating antigens were lower than the BSA. So, the
8
9 4 position of coating antigens (Biotin-BSA conjugates) was significant different than
10
11 5 the BSA and the offset in the position between coating antigens (Biotin-BSA
12
13 6 conjugates) and BSA confirmed the success of the experiment. The coating antigen
14
15 7 with more Biotin-NHS conjugated to BSA would take lower migration rate, which
16
17 8 lead to bigger different of the position on gel.
18
19

20
21 9 The standard curve, IC_{50} , LOD, and CR values of mAb were determined by
22
23 10 ic-ELISA. The standard curve is shown in Figure 2B. Under optimized conditions,
24
25 11 IC_{50} was 0.218 $\mu\text{g}/100\text{ g}$, LOD was 0.038 $\mu\text{g}/100\text{ g}$, and the linear range was 0.096–
26
27 12 0.64 $\mu\text{g}/100\text{ g}$. The ic-ELISA results revealed that mAb had no CR with other B
28
29 13 vitamins; therefore, the mAb generated in our study was both sensitive and specific
30
31 14 for biotin detection.
32
33

34
35

36 **Optimization of the immunochromatographic strip**

37
38 17 The sensitivity of the immunochromatographic strip is mainly affected by the coating
39
40 18 antigens and GNP-mAbs. Coating antigens at different ratios (BSA:Biotin-NHS; 1:2,
41
42 19 1:4, 1:8 M:M) were sprayed on the T line at 0.5 mg/ml. The strips were evaluated
43
44 20 with 0.01 M PBS containing either 0 or 1.0 $\mu\text{g}/100\text{ g}$ biotin. At 1:8 BSA:Biotin-NHS,
45
46 21 the coating antigen resulted in a strong color intensity at the T line in the negative
47
48 22 samples (Figure 3A). In the positive samples (1.0 $\mu\text{g}/100\text{ g}$ biotin), the T line color
49
50 23 intensity became weaker, especially at 1:8 BSA:Biotin-NHS. Therefore, 1:8
51
52 24 BSA:Biotin-NHS was selected for further immunochromatographic strip assays as a
53
54 25 result of the stronger color intensity of the T line with the negative sample and the
55
56
57
58
59
60

1
2
3 1 weakest color intensity of the T line with the positive sample.
4

5 2 Coating antigen concentration was optimized. Strips with different coating antigen
6 concentrations (0.25, 0.5, 1, and 2 mg/ml) on the T line were evaluated with 0.01 M
7 PBS containing either 0 or 1.0 $\mu\text{g}/100\text{ g}$ biotin. At 0.5, 1, and 2 mg/ml coating antigen,
8 defined T red lines were observed. At 0.25 mg/ml coating antigen, the color intensity
9 of the T line was weak. Significant differences in color intensity between the positive
10 and negative samples were obtained at 0.5 mg/ml coating antigen. Compared to the
11 negative sample, the positive sample had weaker color intensity on the T line,
12 suggesting that a more sensitive detection could be achieved at 0.5 mg/ml coating
13 antigen. Therefore, 0.5 mg/ml coating antigen was selected for the preparation of the
14 T line on immunochromatographic strip (Figure 3B).
15
16
17
18
19
20
21
22
23
24
25
26

27 12 GNP-labelled mAb concentration affects immunochromatographic strip sensitivity.
28 GNP-labelled mAb was prepared under optimized conditions, i.e., with 60 μl of 0.1 M
29 K_2CO_3 and 150 μg mAb per 10-ml conjugation system. Each conjugated system (10
30 ml, pH 9.0) was ultimately dissolved in 1 ml gold-labelled re-suspension buffer. The
31 reaction system (50 μl), which contained different volumes of GNP-labelled mAb (2,
32 4, 6, and 8 μl), was allowed to react with positive (1.0 $\mu\text{g}/100\text{ g}$) and negative (0
33 $\mu\text{g}/100\text{ g}$) samples (Figure 3C). At 2 and 4 μl GNP-labelled mAb, the T and C lines
34 had weak color intensities. At 8 μl GNP-labelled mAb, the cut-off value of the strips
35 increased. At 6 μl GNP-labelled mAb, we obtained strong color intensities on both
36 lines with the negative sample and more sensitive detection with the positive sample.

1 Analytical characteristics of the immunochromatographic strip

2 Milk and milk product samples were first tested by the microbiological assay method.
3 Biotin content in each sample was confirmed by the Chinese national food safety
4 standard GB 5413.19-2010. The raw milk samples with the lowest biotin content
5 (1.01 $\mu\text{g}/100\text{ g}$) was selected for the analyses.

6 Selected raw milk samples were spiked with different concentrations of biotin,
7 resulting in final biotin concentrations of 1.01, 2.0, 4.0, 8.0, 16.0, 32.0, 64.0 $\mu\text{g}/100\text{ g}$
8 raw milk. These samples were analyzed by the immunochromatographic strip assay.

9 In the semi-quantitative assay, the vLOD and cut-off values in the raw milk
10 sample were 2.0 $\mu\text{g}/100\text{ g}$ and 8.0 $\mu\text{g}/100\text{ g}$, respectively (Figure 4). In the
11 quantitative assay, cLOD was 0.32 $\mu\text{g}/100\text{ g}$ and the linear range was 0.65–68 $\mu\text{g}/100$
12 g (Figure 5).

13 Sample analysis

14 All the samples confirmed by the microbiological assay method against the national
15 standard were analyzed by the immunochromatographic strip assay with 0.01 M PBS
16 as the control sample. In the semi-quantitative assay, negative (-), weakly positive (\pm),
17 and positive (+) results could be obtained. In the quantitative assay, the optical density
18 of the T lines were measured with a strip scan reader and the results were calculated
19 (Table 1).

20 Based on the semi-quantitative results, there were no positive raw milk or pure
21 milk samples, except for sample P2. Infant milk powder and instant whole cream milk
22 powder samples were biotin-positive, because these samples are generally fortified
23 with the B vitamin. The vLOD and cut-off values of the developed
24 immunochromatographic strip were 2.0 $\mu\text{g}/100\text{ g}$ and 8.0 $\mu\text{g}/100\text{ g}$, respectively.
25

1
2
3 1 Based on these results, it is difficult to confirm whether the content of biotin in dairy
4
5 2 products meets the national standard guidelines.
6

7 3 On the other hand, more sensitive results could be obtained by the quantitative
8
9 4 assay. As shown in Table 1, the quantitative assay revealed that biotin concentration in
10
11 5 some of the milk products was 77–118 % of the national standard guidelines.
12

13 6 For each type of samples, one sample was randomly chosen (R2, P4, I1, M2) and
14
15 7 different concentration of Biotin was spiked into these samples. All the samples were
16
17 8 tested by both national standard and immunochromatographic strip assay. The result
18
19 9 was shown in Table 2. The recoveries ranging from 68% to 119% based on the
20
21 10 national standard. And in liquid samples (R2, P4) the recovery rate was better than the
22
23 11 in powder samples (86% to 112% compared with 68% to 119%). This may be caused
24
25 12 by the different production process of different products.
26
27

28 13 Compared to the microbiological assay method, our developed
29
30 14 immunochromatographic strip assay was rapid and sensitive for biotin detection in
31
32 15 milk and milk products. Even though the microbiological assay method has been
33
34 16 developed into a commercial detection kit (VitaFast® Vitamin B7 Biotin kit,
35
36 17 R-Biopharm Co., Ltd., Germany), the entire detection process requires 46–50 h and
37
38 18 the LOD value is 0.013 µg/100 g (mL) with a linear range of 0.08–0.72 µg/100 g (ml).
39
40 19 The detection principle was the same as the national standard. On the other hand, the
41
42 20 results from the immunochromatographic test assay can be obtained in 20 min,
43
44 21 making it suitable for on-site biotin detection in milk and milk product samples.
45
46
47
48
49
50

51 52 **Conclusions**

53
54 24 A competitive immunochromatographic strip assay was developed for the detection of
55
56 25 biotin in foods. The vLOD and cut-off values of our developed method were 2.0
57
58
59
60

1
2
3 1 $\mu\text{g}/100\text{ g}$ and $8.0\ \mu\text{g}/100\text{ g}$, respectively, in milk samples. Based on the quantitative
4
5 2 results, cLOD was $0.32\ \mu\text{g}/100\text{ g}$ and the linear range was $0.65\text{--}68\ \mu\text{g}/100\text{ g}$. Our
6
7 3 developed method was successfully applied to the detection of biotin in milk and milk
8
9
10 4 products. The results were in good agreement with the microbiological assay method.
11
12 5 In summary, the immunochromatographic strip assay represents a sensitive and rapid
13
14 6 detection method, which is suitable for on-site detection and rapid initial screening of
15
16 7 biotin in milk and milk product samples.
17
