Lipase-modified pH responsive poly (N-isopropylacrylamide)-based microgels were synthesized. An optical device was subsequently fabricated by sandwiching the enzyme loaded responsive microgels between two thin Au layers, and their response to triolein, a model triglyceride, was investigated. The device’s response depended on the triglyceride concentration, demonstrating its potential application as a triglyceride biosensor.

Triacylglycerols (TAGs) are triesters of glycerol and fatty acids, with typical chain lengths of 12-18 carbon atoms and degrees of unsaturation varying between 0 and 6.1 TAGs are a primary component of vegetable and animal lipids and hence a critical constituent of the human diet. TAGs are metabolized via hydrolysis by pancreatic lipase and biosynthesized into lipoproteins often classified as high-density lipoprotein (HDL) and low-density lipoprotein (LDL). The lipoproteins act as mobilizers of useful lipophilic entities such as cholesterol in the body. High levels of TAGs in serum, especially saturated TAGs, are directly linked to elevated LDL, which could create a highly atherogenic state ultimately leading to increased risk of heart attack. 2, 3 Also, from epidemiological studies,4 it is evident that elevated TAG levels in serum is associated with various cardiovascular diseases. For example, high concentrations of TAG can cause coronary diseases and disorders including diabetes mellitus nephrosis, liver obstruction and endocrine pathologies. Therefore, a sensitive and selective method to determine TAG concentration is essential for more effective and rapid clinical diagnosis.

Conventionally, TAGs are analysed by Lewis acid catalysed methylation followed by gas chromatography (GC) analysis; this is a lengthy analytical process. The IUPAC method for TAG analysis uses high performance liquid chromatography (HPLC) coupled with refractive index (RI) detection.5 Since this method uses isocratic elution, analysis times are generally long, especially for mixtures containing long chain triglycerides. HPLC methods employing gradient elution with UV detection have provided faster separations than with refractive index.6 However, due to the low wavelengths necessary for triglyceride detection (for example, 210 nm), UV analysis is very susceptible to baseline drift under gradient elution. In addition, the choice of mobile phase solvents is limited at lower wavelengths.

Recently, biosensors have attracted considerable attention as they can be made very sensitive, and specific, while many are simple and easy to use and can be very cost effective.7 Thus far, very few TAG biosensors that utilize immobilized TAG enzymes have been reported in the literature.8, 9 Instead, existing biosensors typically take advantage of two main reactions. First, TAGs are hydrolyzed into glycerol and fatty acids in the presence of lipase. Then, the glycerol level is quantitatively determined via, e.g., colorimetry, fluorimetry and/or amperometry.10

The device's response to triolein, a model triglyceride, was investigated. The device's response depended on the triglyceride concentration, demonstrating its potential application as a triglyceride biosensor.

Triacylglycerols (TAGs) are triesters of glycerol and fatty acids, with typical chain lengths of 12-18 carbon atoms and degrees of unsaturation varying between 0 and 6.1 TAGs are a primary component of vegetable and animal lipids and hence a critical constituent of the human diet. TAGs are metabolized via hydrolysis by pancreatic lipase and biosynthesized into lipoproteins often classified as high-density lipoprotein (HDL) and low-density lipoprotein (LDL). The lipoproteins act as mobilizers of useful lipophilic entities such as cholesterol in the body. In addition, the choice of mobile phase solvents is limited at lower wavelengths.

Recently, biosensors have attracted considerable attention as they can be made very sensitive, and specific, while many are simple and easy to use and can be very cost effective.7 Thus far, very few TAG biosensors that utilize immobilized TAG enzymes have been reported in the literature.8, 9 Instead, existing biosensors typically take advantage of two main reactions. First, TAGs are hydrolyzed into glycerol and fatty acids in the presence of lipase. Then, the glycerol level is quantitatively determined via, e.g., colorimetry, fluorimetry and/or amperometry.10

The Serpe Group pioneered the development of a novel optical device (etalon), which can be fabricated by sandwiching a single layer of poly (N-isopropylacrylamide) (pNIPAm)-based hydrogel particles (microgels) between two semi-transparent thin gold (Au) layers. These devices have found many applications, including for sensing and biosensing.14-19 The structure of an etalon can be seen in Scheme 1a.14, 15 In short, these devices are constructed by "painting" a concentrated microgel solution onto a Au-coated glass substrate, followed by rinsing away the excess microgels not attached directly to the Au. After additional soaking and rinsing, the microgel layer was dried, and a subsequent layer of Au deposited on the microgel layer. These devices show visible color and unique multiplex reflectance spectra. The position and order of the peaks can be predicted from eqn (1):

$$\lambda = 2nd \cos \theta/m$$

where n is the refractive index of the dielectric layer, d is the mirror–mirror distance, \( \theta \) is the angle of incident light relative to the normal, and m (an integer), is the order of the reflected peak. Therefore, the size change of these microgels translates into a wavelength shift of the reflectance peaks. We point out here that
the distance between the two Au layers dominates the etalons optical properties, and the refractive index change has a negligible influence on the peaks position.

In this submission, TAG-responsive etalons were fabricated; to accomplish this, lipase modified microgels were synthesized. Briefly, microgels with diameters of around 2 μm (determined by dynamic light scattering (DLS)) were prepared by free radical precipitation polymerization of N-isopropylacrylamide (NIPAm), 4-vinylpyridine, N,N'-methylenebis(acrylamide) (crosslinker) and N-acryloxysuccinimide, as shown in Scheme 1. Lipase was covalently conjugated to microgels by reaction of the –NH2 on lipase with N-oxysuccinimide on the microgels. Transmission electron microscope (TEM) images of these microgels are shown in Figure 1. As can be seen, in both cases, the microgels are spherical, with average dry diameters of 1100 nm for enzyme free microgels (MG) and 900 nm for microgels loaded with lipase (MG-Lipase) (via analysis of the microscope images). The microgel sizes were also characterized by DLS (Figure S1 and S2). The DLS revealed hydrodynamic diameters of 2054 ± 50 nm for MG and 1843 ± 45 nm for MG-Lipase in their swollen state (at 30 °C). These values are averages of three repeat analyses of the microgels. The decrease in the microgel hydrodynamic diameter after lipase incorporation was attributed to the ability of lipase to crosslink inside the microgels. Specifically, lipase contains many amine groups (-NH2) that can react with N-oxysuccinimide of microgels. In this case, it can crosslink the microgels, causing them to decrease in diameter. The content of lipase in microgels was determined by Lowry protein assay (Supporting Information). The result showed that lipase was quantitatively incorporated into microgels. Therefore, the content of lipase in microgels can be controlled by tuning N-acryloxysuccinimide ratio in reactants.

Microgel-based etalons were subsequently constructed from the MG-Lipase, and their responsivity to triolein (a model TAG) was investigated. The resulting reflectance spectra of the devices at 30 °C are shown in Figure 2. As can be seen, a characteristic multipeak reflectance spectrum was observed, with peaks at 453 nm, 600 nm, and 850 nm at 30 °C. From the relative positions of the reflectance peaks, and using eqn (1), the order (m) of each peak can be calculated. The peak at 600 nm is m = 3 (noted as λ3), λ2 is 453 nm, while λ3 is 850 nm. When conducting these experiments, it is important to compare the same order peaks before and after introduction of TAG. As can be seen from Figure 2a, 180 nm blue-shift of λ3 occurred after exposure to triglycerides. We propose that triolein was hydrolyzed into long chain fatty acid (C18H34COOH) by lipase inside the microgels. The long chain fatty acid could subsequently attach to the microgels via acid-base reaction between fatty acid and the microgel's pyridine groups. The lipophilicity of long chain fatty acid increases the hydrophobicity of microgels, hence water was expelled from the microgels, and they collapsed. This resulted in a blue shift of the etalon's reflectance peaks.

![Figure 1 TEM images of (left) lipase free microgels and (right) microgels with lipase loaded. Scale bar is 1 μm.](image)

![Figure 2 (a) Reflectance spectra of etalon after exposure to triolein (9 mg/mL) at 30 °C after the indicated times; (b) λ3 blue-shift as function of triglyceride concentration.](image)

![Figure 3 (a) Response time and λ3 blue-shift as function of temperature; (b) λ3 blue-shift as function of the number of times used.](image)
the lipase in the microgels less accessible, requiring more time for the enzymatic reaction and fatty acid generation. The fact that the microgels are already in a collapsed state above the LCST, also leads to the observed decrease in the magnitude of the response.

In another experiment, we determined if the device could be used multiple times to detect triolein. To "regenerate" the etalon after use, it was exposed to K$_2$HPO$_4$/KH$_2$PO$_4$ buffer solution (pH 8, H$_2$O/EtOH = 1:1) to remove the long chain fatty acids ($C_{18:1}$ COOH) from the pyridine groups. As can be seen in Figure 3b, the same device could be used at least 5 times without any significant loss of response (~3.4%).

In summary, pyridine-containing microgels were synthesized, and lipase covalently attached to the microgels. Etalons were fabricated by sandwiching these microgels between two thin Au layers, following established protocols. The resultant etalons were shown to exhibit a response to the presence, and concentration, of a triglyceride. We showed that the extent of the response varied systematically with triglyceride concentration, indicating its potential application as triglyceride biosensor. Due to their low cost ~0.04 CAD/square inch and ease of use, these devices could find real world applications in a clinical setting.
