This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard Terms \& Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.

# Dimetallaborane Analogues of Pentaborane ${ }^{\dagger}$ 

Adrian M. V. Brânzanic, ${ }^{1}$ Alexandru Lupan, ${ }^{* 1}$ and R. Bruce King* ${ }^{2}$<br>${ }^{1}$ Department of Chemistry, Faculty of Chemistry and Chemical Engineering, BabeşBolyai University, Cluj-Napoca, Romania<br>${ }^{2}$ Department of Chemistry, University of Georgia, Athens, Georgia, 30602

#### Abstract

The structures of five-vertex dimetallaboranes $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}\left(\mathrm{Cp}=\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)$ of the second and third row transition metals, including the experimentally known $\mathrm{Cp}^{*}{ }_{2} \mathrm{Rh}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}\left(\mathrm{Cp}^{*}=\eta^{5}-\mathrm{Me}_{5} \mathrm{C}_{5}\right)$, have been investigated by density functional theory. The predicted low-energy structures for $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Rh}$, Ir) are tetragonal pyramids similar to $\mathrm{Cp}^{*}{ }_{2} \mathrm{Rh}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ and pentaborane- $9 \mathrm{~B}_{5} \mathrm{H}_{9}$ and consistent with their 14 Wadean skeletal electrons. Two $\mathrm{Cp}^{*}{ }_{2} \mathrm{Rh}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures with the same central $\mathrm{Rh}_{2} \mathrm{~B}_{3}$ tetragonal prism are found with energies within $\sim 1 \mathrm{kcal} / \mathrm{mol}$ of each other consistent with the experimental observation of two isomers in solution. The electron-richer $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}$ $=\mathrm{Pd}, \mathrm{Pt})$ systems having 16 Wadean skeletal electrons are predicted to exhibit more open structures analogous to the known structure for the valence isoelectronic pentaborane-11 $\mathrm{B}_{5} \mathrm{H}_{11}$. Trigonal bipyramids with the metal atoms at equatorial vertices are typically found as low-energy structures for the hypoelectronic $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ systems $(\mathrm{M}=\mathrm{Ru}$, Os, $\mathrm{Re}, \mathrm{Mo}, \mathrm{W}, \mathrm{Ta}$ ). In addition, the low-energy $\mathrm{Cp}_{2} \mathrm{Re}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures of the rhenium derivatives $\mathrm{Cp}_{2} \mathrm{Re}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ provide examples of structures based on a central $\mathrm{Re}_{2} \mathrm{~B}_{2}$ tetrahedron with the Re-Re edge bridged by the third boron atom. Such structures can be derived from a trigonal bipyramid by rupture of one of the axial-equatorial edges.

## 1. Introduction

One of the original binary boron hydrides isolated in the pioneering work of Stock from magnesium boride and acid is pentaborane-9, $\mathrm{B}_{5} \mathrm{H}_{9}$ (Figure 1). ${ }^{1}$ Subsequent major improvements in the synthesis of $\mathrm{B}_{5} \mathrm{H}_{9}$ led to its manufacture in ton quantities as a raw material for borane rocket fuels. In addition, a less stable hydrogen-richer pentaborane$11, \mathrm{~B}_{5} \mathrm{H}_{11}$, was also obtained in the early boron hydride work. ${ }^{2,3}$ The $\mathrm{B}_{5} \mathrm{H}_{9}$ structure has a central $\mathrm{B}_{5}$ tetragonal pyramid whereas the central $\mathrm{B}_{5}$ unit of the $\mathrm{B}_{5} \mathrm{H}_{11}$ structure has been described ${ }^{3}$ as an "open-sided tetragonal pyramid."

Figure 1. Structures of the two known pentaboranes $\mathrm{B}_{5} \mathrm{H}_{9}$ and $\mathrm{B}_{5} \mathrm{H}_{11}$.

Hawthorne and coworkers ${ }^{4}$ were the first to show that boron vertices in 10- to 12-vertex borane deltahedra can be replaced by isolobal transition metal vertices to give stable metallaboranes synthesized using decaborane-14, $\mathrm{B}_{10} \mathrm{H}_{14}$ as the boron hydride starting material for their syntheses. Shortly thereafter Grimes and co-workers ${ }^{5}$ showed that similar metallaboranes could be synthesized based on smaller polyhedra using penta-borane- $9, \mathrm{~B}_{5} \mathrm{H}_{9}$ as the boron hydride starting material.

The initially discovered metallaboranes and dimetallaboranes had structures based on the most spherical so-called closo deltahedra with skeletal electron counts corresponding to the Wade-Mingos rules. ${ }^{6,7,8}$ Thus the underlying polyhedra in most of the initially discovered species were derived from the closo deltahedra found in the metalfree $\mathrm{B}_{n} \mathrm{H}_{n}{ }^{2-}$ dianions ( $n=6$ to 12 ) for which the $n$ vertex systems have $2 n+2$ skeletal electrons. Such deltahedra typically have only degree 4 and 5 vertices with a single degree 6 vertex in the 11 -vertex closo deltahedron being the only exception. Later Kennedy and co-workers ${ }^{9}, 10,11,12$ showed that so-called isocloso hypoelectronic metallaboranes could be obtained with only $2 n$ skeletal electrons for $n$-vertex systems ( $n=9,10$, 11). For the 9 - and 10 -vertex isocloso systems the underlying polyhedra were deltahedra having a single degree 6 vertex for a metal atom. The 9 - and 10 -vertex isocloso deltahedra were found to be different from the 9 - and 10 -vertex closo deltahedra because of the single degree 6 vertex. However, the isocloso and closo 11 -vertex deltahedra are
topologically the same since even the closo 11-vertex deltahedron necessarily has a single degree 6 vertex.

Introducing two transition metal vertices into a metallaborane structure can lead to even more hypoelectronic systems as stable structures. Particularly interesting are the stable dirhenaboranes $\mathrm{Cp}_{2} \mathrm{Re}_{2} \mathrm{~B}_{n-2} \mathrm{H}_{n-2}$ with $2 n-4$ Wadean skeletal electrons first synthesized by Fehlner and coworkers. ${ }^{13,14}$ These dirhenaboranes have flattened deltahedral structures with rhenium atoms at approximately antipodal degree 6 and/or degree 7 vertices with the boron atoms forming an approximately equatorial "belt" consisting largely of degree 4 vertices. Such flattened deltahedral structures, which approximate oblate ellipsoids rather than spheres, are conveniently called oblatocloso structures. ${ }^{15}$

The existence of closo, isocloso, and oblatocloso deltahedra structures with different Wadean skeletal electron counts illustrates the richness of metallaborane chemistry and the strong dependence of polyhedral geometries on the skeletal electron count. We have gone beyond experimentally available information to explore the scope of such metallaborane chemistry using well-established density functional methods. Such studies have included systems corresponding to closo, ${ }^{16,17,18,19}$ isocloso, ${ }^{20,21}$ and oblatocloso ${ }^{22,23}$ systems having $2 n+2,2 n$, and $2 n-4$ Wadean skeletal electron counts, respectively. Additional possibilities arise in so-called hydrogen-rich nido and arachno structures, obtained by removal of one or two vertices, respectively, from a closo deltahedron and flanking the resulting "hole," i. e., a polyhedral face with four or more sides, with the extra hydrogen atoms as bridging hydrogen atoms. The nido and arachno systems are hyperelectronic systems having $2 n+4$ and $2 n+6$ skeletal electrons for $n$-vertex nido and arachno systems, respectively. Both pentaborane- $9, \mathrm{~B}_{5} \mathrm{H}_{9}$, and decaborane, $\mathrm{B}_{10} \mathrm{H}_{14}$ are examples of metal-free nido $\mathrm{B}_{n} \mathrm{H}_{n+4}$ structures.

We have begun to investigate hydrogen-rich dimetallaboranes having diverse Wadean skeletal electron counts using theoretical methods similar to those previously used for various closo, isocloso, and oblatocloso systems. Initially, we have studied $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{n} \mathrm{H}_{n+4}$ systems with four "extra" hydrogen atoms corresponding at least superficially to the metal-free binary nido boranes $\mathrm{B}_{5} \mathrm{H}_{9}$ and $\mathrm{B}_{10} \mathrm{H}_{14}$. The corresponding pentamethylcyclopentadienyl derivatives $\mathrm{Cp}_{2}{ }_{2} \mathrm{M}_{2} \mathrm{~B}_{4} \mathrm{H}_{8}\left(\mathrm{Cp}^{*}=\eta^{5}-\mathrm{Me}_{5} \mathrm{C}_{5} ; \mathrm{M}=\mathrm{Ir}^{24,25}\right.$, $\mathrm{Re},{ }^{26}$ and $\mathrm{Ru}^{27}$ ) are known species, having first been synthesized by Fehlner and coworkers and structurally characterized by X-ray crystallography. Theoretical studies on these hydrogen-rich species, typically based on open polyhedra, are more complicated than our earlier theoretical studies on closed deltahedral systems because of the variety of possible locations of the "extra" hydrogen atoms on the central polyhedron.

Nevertheless, meaningful results have been obtained on the six-vertex open $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{4} \mathrm{H}_{8}$ systems. ${ }^{28}$ The six-vertex $\mathrm{Cp}_{2} \mathrm{Ir}_{2} \mathrm{~B}_{4} \mathrm{H}_{8}$ is predicted to have a central nido $\mathrm{Ir}_{2} \mathrm{~B}_{4}$ pentagonal pyramidal structure in accord with experiment and the $2 n+4$ Wadean skeletal electrons (= 16 for $n=6$ ). The slightly electron poorer $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{4} \mathrm{H}_{8}(\mathrm{M}=\mathrm{Ru}$, Os) systems with only $2 n$ Wadean skeletal electrons $\left(=14\right.$ for $n=6$ ) have a central $\mathrm{M}_{2} \mathrm{~B}_{4}$ tetragonal pyramid capped on one of its triangular faces. The more hypoelectronic $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{4} \mathrm{H}_{8}(\mathrm{M}$ $=\mathrm{Re}, \mathrm{Mo}, \mathrm{W}, \mathrm{Ta})$ systems have central bicapped trigonal bipyramids corresponding to the experimentally known structure ${ }^{26}$ for $\mathrm{Cp}_{2} \mathrm{Re}_{2} \mathrm{~B}_{4} \mathrm{H}_{8}$.

This paper reports a study on the five-vertex systems $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Pd}, \mathrm{Pt}$, $\mathrm{Rh}, \mathrm{Ir}, \mathrm{Ru}, \mathrm{Os}, \mathrm{Re}, \mathrm{Mo}, \mathrm{W}, \mathrm{Ta}$ ) using similar density functional theory methods. The analogous pentamethylcyclopentadienylrhodium system $\mathrm{Cp}^{*}{ }_{2} \mathrm{Rh}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ is experimentally known as a tetragonal pyramidal structure, which can be derived from the pentaborane structure by replacement of the apical BH vertex and one basal BH vertex with isolobal Cp*Rh units. ${ }^{29}$ The temperature dependence of the NMR spectrum suggests a second isomer.

Figure 2. Relationship between the five-vertex polyhedra and the number of skeletal electrons.

The relationship between the possible five-vertex polyhedra for the central $\mathrm{M}_{2} \mathrm{~B}_{3}$ units in the $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures is depicted in Figure 2. The $D_{3 h}$ trigonal bipyramid is the closo five-vertex deltahedron with nine edges and is expected by the Wade-Mingos rules to have 12 skeletal electrons $(=2 n+2$ for $n=5)$. This polyhedron is found in the five-vertex carborane $\mathrm{C}_{2} \mathrm{~B}_{3} \mathrm{H}_{5} .{ }^{30}$ Removal of an equatorial-equatorial edge from the
trigonal bipyramid with accompanying distortion of the vertex locations to $C_{4 v}$ symmetry gives the tetragonal pyramid, which is the nido five-vertex deltahedron found in $\mathrm{B}_{5} \mathrm{H}_{9}$ with 14 Wadean skeletal electrons $(=2 n+4$ for $n=5)$. Alternatively, removal of an axial-equatorial edge from the trigonal bipyramid gives an edge-bridged tetrahedron. If the metal atoms in a $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ derivative with such edge-bridged tetrahedral geometry form the bridged edge of the edge-bridged tetrahedron, then this structure is equivalent to a metal-metal bond bridged both by a single boron atom and a pair of boron atoms. Finally, removal of a basal-basal edge from the square pyramid gives the more open arachno pentaborane-11 structure with 16 skeletal electrons corresponding to $2 n+6$ for $n$ $=5$. This may relate to the lower stability of $\mathrm{B}_{5} \mathrm{H}_{11}$ relative to $\mathrm{B}_{5} \mathrm{H}_{9}$.

## 2. Theoretical Methods

The initial $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures were pentagonal and tetragonal pyramidal structures substituted in all possible ways with two CpM vertices (Table S 1 in the Supporting Information). The extra four hydrogen atoms were then incorporated as edgecapping atoms on the edges of the tetragonal/pentagonal open face or on the metal-metal edge. This led to 35 different starting geometries to be optimized for each metal family as detailed in Table S1 of the Supporting Information file.

Full geometry optimizations were carried on the $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ systems at the B3LYP/6-31G(d) ${ }^{31,32,33,34}$ level for all atoms except the metal for which the SDD (Stuttgart-Dresden ECP plus DZ) basis set ${ }^{35}$ was chosen. The lowest energy structures were then reoptimized at a higher level, i.e. M06L/6-311G(d,p)/SDD and these are the structures presented in the manuscript. ${ }^{36}$ The natures of the stationary points after optimization were checked by calculations of the harmonic vibrational frequencies. If significant imaginary frequencies were found, the optimization was continued by following the normal modes corresponding to imaginary frequencies to insure that genuine minima were obtained. Normally this resulted in reduction of the molecular symmetry.

All calculations were performed using the Gaussian 09 package ${ }^{37}$ with the default settings for the SCF cycles and geometry optimization, namely the fine grid $(75,302)$ for numerically evaluating the integrals, $10^{-8}$ hartree for the self-consistent field convergence, maximum force of 0.000450 hartree/bohr, RMS force of 0.000300 hartree/bohr, maximum displacement of 0.001800 bohr, and RMS displacement of 0.001200 bohr. Wiberg bond indices (WBIs) for the M-M interactions in the optimized
$\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{5} \mathrm{H}_{9}$ structures determined using NBO analysis ${ }^{38}$ were used since they are wellestablished as means for evaluating M-M interactions in polyhedral dimetallaboranes ${ }^{39}$ as well as other binuclear and trinuclear transition metal complexes. ${ }^{40}$

The structures, total and relative energies (M06L/6-311G(d,p)/SDD including zero-point corrections), and relevant interatomic distances for all calculated systems are given in the Supporting Information. Structures are numbered as M2B3-x where $\mathbf{x}$ is the relative order of the structure on the energy scale. Only the lowest energy and thus potentially chemically significant structures (Figures 3 to 8 and Tables 1 to 6) are considered in detail in this paper. However, more comprehensive lists of structures, including higher energy structures, are given in the Supporting Information.

Most of the $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures reported in this paper have three terminal hydrogen atoms (one on each boron atom) and four bridging hydrogen atoms. In the Tables the locations of the bridging hydrogen atoms are designated as $\mathrm{M}_{2}, \mathrm{MB}$, and $\mathrm{B}_{2}$ for hydrogen atoms bridging metal-metal edges, metal-boron edges, and boron-boron edges, respectively.

## 3. Results and Discussion

## 3.1 $\mathbf{C p}_{2} \mathbf{M}_{2} \mathrm{~B}_{3} \mathbf{H}_{7}(\mathbf{M}=\mathbf{P d}, \mathbf{P t})$ structures.

The $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Pd}, \mathrm{Pt})$ systems have 16 Wadean skeletal electrons since each $\mathrm{CpM}(\mathrm{M}=\mathrm{Pd}, \mathrm{Pt})$ vertex contributes three skeletal electrons. They are thus isoelectronic with pentaborane-11, $\mathrm{B}_{5} \mathrm{H}_{11}$, which is an arachno structure having $2 n+6$ Wadean skeletal electrons consistent with the Wade-Mingos rules ${ }^{6,7,8}$ (Figure 2). The three lowest energy $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Pd}, \mathrm{Pt})$ structures M2B3-1, M2B3-2, and M2B3-3 $(M=P d, P t)$ have similar geometries to $\mathrm{B}_{5} \mathrm{H}_{11}$ with the CpM vertices replacing the degree 4 apical BH vertex as well as an "end" basal $\mathrm{BH}_{2}$ vertex (Figure 3 and Table 1). These $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures can be derived from an $\mathrm{M}_{2} \mathrm{~B}_{3}$ square pyramid by lengthening one of the basal M-B edges to at least $3.0 \AA$ so it can be considered to be a non-bonding edge. The boron atom at the end of this lengthened basal "edge" bears two terminal hydrogen atoms similar to the parent $\mathrm{B}_{5} \mathrm{H}_{11}$. In Pd2B3-1 and the corresponding Pt2B3-2 an M-B edge in addition to two $\mathrm{B}-\mathrm{B}$ edges is bridged by hydrogen atoms. However, in Pd2B3-2 and the corresponding Pt2B3-1 an $\mathrm{M}-\mathrm{M}$ edge in addition to two $\mathrm{B}-\mathrm{B}$ edges are bridged by hydrogen atoms. Structures M2B3-3 $(\mathrm{M}=\mathrm{Pd}, \mathrm{Pt})$ have two $\mathrm{BH}_{2}$ groups with a nonbonding $\mathrm{B} \cdots \mathrm{B}$ distance of $\sim 3.0 \AA$ between them. For comparison, the analogous nonbonding distance between the two $\mathrm{BH}_{2}$ groups in $\mathrm{B}_{5} \mathrm{H}_{11}$ is $3.091(10) \AA$, as determined by electron diffraction in the gas phase. ${ }^{3}$

Table 1. The three optimized $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Pd}$, Pt$)$ structures within $12 \mathrm{kcal} / \mathrm{mol}$ of the global minima with relative energies in $\mathrm{kcal} / \mathrm{mol}$.

Figure 3. The three $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Pd}, \mathrm{Pt})$ structures within $12 \mathrm{kcal} / \mathrm{mol}$ of the global minima.

## 3.2 $\mathbf{C p}_{2} \mathbf{M}_{2} \mathbf{B}_{3} \mathbf{H}_{7}(\mathbf{M}=\mathbf{R h}$, $\mathbf{I r})$ structures.

The $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Rh}, \mathrm{Ir})$ structures have 14 Wadean skeletal electrons since each CpM vertex contributes two skeletal electrons. They thus are isoelectronic with pentaborane-9, $\mathrm{B}_{5} \mathrm{H}_{9}$, which is a nido tetragonal pyramidal structure having $2 n+4$ skeletal electrons (Figure 2). All four low-energy $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Rh}$, Ir) structures have central tetragonal pyramidal $\mathrm{M}_{2} \mathrm{~B}_{3}$ units consistent with the Wade-Mingos rules ${ }^{6,7,8}$ (Figure 4). Furthermore, the pentamethylcyclopentadienyl derivative $\mathrm{Cp}^{*}{ }_{2} \mathrm{Rh}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}\left(\mathrm{Cp}^{*}\right.$ $=\eta^{5}-\mathrm{Me}_{5} \mathrm{C}_{5}$ ) has been synthesized and structurally characterized by X-ray crystallography. ${ }^{29}$

Two of the four low-energy $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Rh}, \mathrm{Ir})$ structures (M2B3-1 and M2B3-3) have one metal atom in the apex and the other metal atom in the base of the central $\mathrm{M}_{2} \mathrm{~B}_{3}$ tetragonal pyramid (Figure 4). The remaining two such structures M2B3-2 and M2B3-4 have both metal atoms in the base of the $\mathrm{M}_{2} \mathrm{~B}_{3}$ tetragonal pyramid. The experimental $\mathrm{Cp}_{2}{ }_{2} \mathrm{Rh}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structure corresponds to M2B3-1 with hydrogen atoms bridging all four basal edges of the $\mathrm{M}_{2} \mathrm{~B}_{3}$ tetragonal pyramid. ${ }^{29}$ In order to have a better theoretical model for the experimental system the four lowest energy $\mathrm{Cp}_{2} \mathrm{Rh}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures were reoptimized after replacing both Cp ligands with $\mathrm{Cp} *$ ligands (Table 2).

The predicted $\mathrm{Rh}-\mathrm{Rh}$ distance in the optimized $\mathrm{Cp}^{*}{ }_{2} \mathrm{Rh}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structure of $2.689 \AA$ is remarkably identical to the experimental distance of $2.6892(3) \AA$ as determined by X-ray crystallography. ${ }^{29}$

Figure 4. The four $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Rh}, \mathrm{Ir})$ structures within $30 \mathrm{kcal} / \mathrm{mol}(\mathrm{M}=\mathrm{Rh})$ or $20 \mathrm{kcal} / \mathrm{mol}(\mathrm{M}=\mathrm{Ir})$ of the global minima.

Table 2. The four optimized $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Rh}$, Ir$)$ structures within $30 \mathrm{kcal} / \mathrm{mol}(\mathrm{M}$ $=\mathrm{Rh})$ or $20 \mathrm{kcal} / \mathrm{mol}(\mathrm{M}=\mathrm{Ir})$ of the global minima with relative energies in $\mathrm{kcal} / \mathrm{mol}$. All of these structures have central $\mathrm{M}_{2} \mathrm{~B}_{3}$ tetragonal pyramids.

| $\mathbf{a}$ |  |  |  |  |  |  |  |  |  |

${ }^{\mathbf{a}}$ The $\Delta \mathrm{E}$ values for the corresponding permethylated $\mathrm{Cp}^{*}{ }_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ derivatives are given in parentheses.

The experimental work on $\mathrm{Cp}^{*}{ }_{2} \mathrm{Rh}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ suggests the existence of a second isomer in solution in addition to the isomer corresponding to $\mathbf{R h} 2 \mathbf{B 3} \mathbf{- 1}$ observed in the solid state. ${ }^{29}$ The temperature-dependence of its proton NMR spectrum suggests a structure analogous to Rh2B3-3 in which a hydrogen atom has migrated from a basal Rh-B edge to a basal-apical Rh-Rh edge. Substituting all of the ring hydrogen atoms with methyl groups in $\mathrm{Cp}_{2} \mathrm{Rh}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ with methyl groups to give $\mathrm{Cp}^{*}{ }_{2} \mathrm{Rh}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ reduces the predicted energy difference between Rh2B3-1 and Rh2B3-3 from $6.8 \mathrm{kcal} / \mathrm{mol}$ in $\mathrm{Cp}_{2} \mathrm{Rh}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ to only $1.6 \mathrm{kcal} / \mathrm{mol}$ (Table 2). It is therefore not surprising that both isomers are observed experimentally in the $\mathrm{Cp}^{*}{ }_{2} \mathrm{Rh}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ system. Note that interconversion between the low-energy $\mathbf{R h} 2 \mathbf{B 3} \mathbf{- 1}$ and $\mathbf{R h} 2 \mathbf{B 3} \mathbf{- 2}$ isomers is expected to be more difficult than the interconversion between Rh2B3-1 and Rh2B3-3. Thus
interconversion between $\mathbf{R h} 2 \mathbf{B 3}-1$ and $\mathbf{R h} 2 \mathbf{B 3}$-2 requires movement of the $\mathrm{Rh}_{2}$ subunit in the underlying tetragonal pyramid from an apical-basal edge to a basal-basal edge whereas interconversion between $\mathbf{R h} 2 \mathbf{B 3 - 1}$ and $\mathbf{R h} 2 \mathbf{B 3} 3$-3 only requires migration of a bridging hydrogen without affecting the underlying $\mathrm{Rh}_{2} \mathrm{~B}_{3}$ tetragonal pyramid skeleton.

## 3.3 $\mathbf{C p}_{2} \mathbf{M}_{2} \mathbf{B}_{3} \mathbf{H}_{7}(\mathbf{M}=\mathbf{R u}$, Os) structures.

The $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Ru}$, Os) structures have 12 Wadean skeletal electrons since each CpM vertex contributes a single skeletal electron. The Wade-Mingos rules ${ }^{6,7,8}$ suggest trigonal bipyramidal structures similar to the known carborane ${ }^{30} \mathrm{C}_{2} \mathrm{~B}_{3} \mathrm{H}_{5}$. Indeed the lowest energy $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Ru}$, Os) structures M2B3-1 have such trigonal bipyramidal geometry with the metal atoms at two of the degree 4 equatorial vertices (Figure 5). This is consistent with the general preference of transition metals for higher degree vertices relative to boron atoms.

Ru2B3-1 ( $C_{1}$ ) $0.0 \mathrm{kcal} / \mathrm{mol}$ Os2B3-1 ( $C_{1}$ ) $0.0 \mathrm{kcal} / \mathrm{mol}$

Ru2B3-2 ( $C_{2 v}$ ) $6.5 \mathrm{kcal} / \mathrm{mol}$ Os2B3-2 ( $\mathrm{C}_{2 \mathrm{v}}$ ) $3.1 \mathrm{kcal} / \mathrm{mol}$

Ru2B3-3 ( $C_{1}$ ) $8.9 \mathrm{kcal} / \mathrm{mol}$ Os2B3-3 ( $C_{1}$ ) $5.3 \mathrm{kcal} / \mathrm{mol}$

Figure 5. The three $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Ru}$, Os ) structures within $9 \mathrm{kcal} / \mathrm{mol}$ of the global minima.

Table 3. The three optimized $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Ru}$, Os$)$ structures within $9 \mathrm{kcal} / \mathrm{mol}$ of the global minima with relative energies in $\mathrm{kcal} / \mathrm{mol}$.

| Structure (symmetry) | Polyhedron | Hydrogen <br> Bridges | $\mathrm{Cp}_{2} \mathrm{Ru}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ |  |  | $\mathrm{Cp}_{2} \mathrm{Os}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | $\Delta \mathrm{E}$ | $\mathrm{Ru}-\mathrm{Ru}$ | WBI | $\Delta \mathrm{E}$ | Os-Os | WBI |
| M2B3-1 ( $C_{1}$ ) | Trigonal bipyramid | $\mathrm{M}_{2} / 2 \mathrm{MB} / \mathrm{B}_{2}$ | 0.0 | 2.788 | 0.33 | 0.0 | 2.857 | 0.36 |
| M2B3-2 ( $C_{2 v}$ ) | Tetragonal pyramid | 4MB | 6.5 | 3.090 | 0.31 | 3.1 | 3.530 | 0.28 |
| M2B3-3 $\left(C_{1}\right)$ | Edge-bridge Tetrahed | $2 \mathrm{MB} / \mathrm{B}_{2}$ | 8.9 | 2.750 | 0.37 | 5.3 | 2.810 | 0.39 |

Other $\mathrm{M}_{2} \mathrm{~B}_{3}$ polyhedra are found in low-energy $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Ru}$, Os) structures (Figure 5 and Table 3). Thus the structures M2B3-2 ( $\mathrm{M}=\mathrm{Ru}$, Os), lying $6.5 \mathrm{kcal} / \mathrm{mol}(\mathrm{M}=\mathrm{Ru})$ and $3.1 \mathrm{kcal} / \mathrm{mol}(\mathrm{M}=\mathrm{Os})$ in energy above M2B3-1, have central
$\mathrm{M}_{2} \mathrm{~B}_{3}$ tetragonal pyramids with the metal atoms in diagonal basal positions. Similarly the structures M2B3-3 ( $\mathrm{M}=\mathrm{Ru}$, Os), lying $8.9 \mathrm{kcal} / \mathrm{mol}(\mathrm{M}=\mathrm{Ru})$ and $5.3 \mathrm{kcal} / \mathrm{mol}(\mathrm{M}=\mathrm{Os})$ in energy above M2B3-1, have a central $\mathrm{M}_{2} \mathrm{~B}_{2}$ tetrahedron with the $\mathrm{M}-\mathrm{M}$ edge bridged by the third boron atom. Alternatively, structures M2B3-3 ( $\mathrm{M}=\mathrm{Ru}$, Os ) can be formulated as $\mathrm{Cp}_{2} \mathrm{M}_{2}\left(\mu-\mathrm{BH}_{2}\right)\left(\mu-\mathrm{B}_{2} \mathrm{H}_{5}\right)$ having an $\mathrm{M}-\mathrm{M}$ bond bridged by both $\mathrm{BH}_{2}$ and $\mathrm{B}_{2} \mathrm{H}_{5}$ groups. These bridges can be interpreted as bonded to the $\mathrm{M}_{2}$ unit using three three-center twoelectron MBH bonds, one four-center two-electron $\mathrm{M}_{2} \mathrm{~B}_{2}$ bond at the center of the $\mathrm{M}_{2} \mathrm{~B}_{2}$ tetrahedron, and one two-electron two-center $\mathrm{M}-\mathrm{B}$ bond to the bridging $\mathrm{BH}_{2}$ group. For the purpose of electron bookkeeping, this complicated extensively delocalized multicenter bonding scheme can be somewhat artificially dissected into a formal $\mathrm{M}-\mathrm{M}$ single bond, a three-electron donor bridging $\mathrm{BH}_{2}$ group, and a five-electron donor bridging $\mathrm{B}_{2} \mathrm{H}_{5}$ group. This gives each metal atom in M2B3-3 $(\mathrm{M}=\mathrm{Ru}$, Os) the favored 18 -electron configuration and is consistent with the WBIs of $\sim 0.38$ for the $\mathrm{M}-\mathrm{M}$ interactions.

## 3.4 $\mathbf{C p}_{2} \mathbf{R e}_{2} \mathbf{B}_{3} \mathbf{H}_{7}$ structures.

The $\mathrm{Cp}_{2} \mathrm{Re}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ system is highly electron deficient if the Wade-Mingos rules ${ }^{6,7,8}$ are blindly applied, since there are only 10 skeletal electrons after realizing that CpRe vertices are donors of zero Wadean electrons. This electron deficiency can be relieved by surface Re-Re multiple bonding, which is recognized by short Re-Re distances and WBIs much higher than 0.4. The possibility of surface multiple bonding in dimetallaboranes was originally suggested by high-energy $\mathrm{Cp}_{2} \mathrm{Re}_{2} \mathrm{~B}_{n} \mathrm{H}_{n}(n=7,8,9,10)$ structures, ${ }^{22}$ characterized more fully in their technetium analogues, ${ }^{23}$ and found in the lowest energy $\mathrm{PnRe}_{2} \mathrm{~B}_{n} \mathrm{H}_{n}$ structures. ${ }^{41}$ In the last structures, Pn is a bis(pentahapto) $\eta^{5}, \eta^{5}-\mathrm{C}_{8} \mathrm{H}_{6}$ pentalene ligand forcing the two rhenium atoms to remain within bonding distance. The variety of $\mathrm{Re}-\mathrm{Re}$ multiple bonding opportunities and possible polyhedra lead to a more complicated potential energy surface than those of the other $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ systems reported in this paper. Thus there are eight $\mathrm{Cp}_{2} \mathrm{Re}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures within $10 \mathrm{kcal} / \mathrm{mol}$ of the global minimum (Figure 6 and Table 4).

The two lowest energy $\mathrm{Cp}_{2} \mathrm{Re}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures $\operatorname{Re2B3-1}$ and $\operatorname{Re2B3} \mathbf{- 2}$, as well as the higher energy structures Re2B3-6 and Re2B3-7 at $\sim 6 \mathrm{kcal} / \mathrm{mol}$ in energy above Re2B3-1, all have a central edge-bridged tetrahedron similar to the $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures M2B3-3 ( $\mathrm{M}=\mathrm{Ru}$, Os) discussed above (Figures 5 and 6). Interpreting these four structures as $\mathrm{Cp}_{2} \mathrm{Re}_{2}\left(\mu-\mathrm{BH}_{2}\right)\left(\mu-\mathrm{B}_{2} \mathrm{H}_{5}\right)$ with a three-electron donor $\mu-\mathrm{BH}_{2}$ group and a five-electron donor $\mu-\mathrm{B}_{2} \mathrm{H}_{5}$ group implies that a formal $\mathrm{Re}=\mathrm{Re}$ double bond is required to give each rhenium atom the favored 18 -electron configuration. This is consistent with
$\mathrm{Re}=\mathrm{Re}$ distances of $\sim 2.6 \AA$ for the four $\mathrm{Cp}_{2} \mathrm{Re}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures Re2B3-1, Re2B3-2, Re2B3-6, and Re2B3-7 (Table 4) as compared with the Os-Os distance of $\sim 2.8 \AA$ for Os2B3-3 (Table 3). In addition, the WBIs of $\sim 0.8$ for the four $\mathrm{Cp}_{2} \mathrm{Re}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures are approximately twice the 0.39 WBI for the $\mathrm{Cp}_{2} \mathrm{Os}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structure $\mathbf{O s} 2 \mathrm{~B} 3-3$. This provides additional support of the presence of formal $\mathrm{Re}=\mathrm{Re}$ double bonds in these $\mathrm{Cp}_{2} \mathrm{Re}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures.

Figure 6. The eight $\mathrm{Cp}_{2} \mathrm{Re}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures within $10 \mathrm{kcal} / \mathrm{mol}$ of the global minimum.

Both trigonal bipyramidal and tetragonal pyramidal $\mathrm{Cp}_{2} \mathrm{Re}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures are found (Figure 6 and Table 4). The two trigonal bipyramidal $\mathrm{Cp}_{2} \mathrm{Re}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures Re2B3-3 and Re2B3-4, lying $\sim 4 \mathrm{kcal} / \mathrm{mol}$ in energy above Re2B3-1, have the rhenium atoms at two of the equatorial positions similar to the likewise trigonal bipyramidal $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Ru}$, Os) structures M2B3-1. (Figure 5 and Table 3). The tetragonal pyramidal $\mathrm{Cp}_{2} \mathrm{Re}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structure $\mathbf{R e 2 B 3 - 5}$, lying $4.8 \mathrm{kcal} / \mathrm{mol}$ in energy above $\mathbf{R e 2 B 3 - 1}$, has a $\mathrm{Re} \equiv \mathrm{Re}$ apical-basal edge. However, the likewise tetragonal pyramidal $\mathrm{Cp}_{2} \mathrm{Re}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structure Re2B3-8, lying $6.4 \mathrm{kcal} / \mathrm{mol}$ in energy above Re2B3-1, has a $\operatorname{Re} \equiv \operatorname{Re}$ basalbasal edge. Both of these $\mathrm{Re} \equiv \operatorname{Re}$ edges are rather short at $\sim 2.45 \AA$ with high WBIs of $\sim 1.4$ suggesting multiple bonding. Interpreting these $\operatorname{Re} \equiv \operatorname{Re}$ edges as formal triple bonds provides an extra four skeletal electrons so that these tetragonal pyramidal structures
(Re2B3-5 and Re2B3-8) have the 14 skeletal electrons required by the Wade-Mingos rules ${ }^{6,7,8}$ for a tetragonal pyramid. Comparing the two tetragonal pyramidal $\mathrm{Cp}_{2} \mathrm{Re}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures with the tetragonal pyramidal $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures ( $\mathrm{M}=\mathrm{Rh}$, Ir) (Figure 4) shows that the formal $\operatorname{Re} \equiv \operatorname{Re}$ triple bond relative to the formal $\mathrm{M}-\mathrm{M}$ single bonds ( $\mathrm{M}=$ $\mathrm{Rh}, \mathrm{Ir}$ ) compensates for the two fewer valence electrons provided by the group 7 metal rhenium as compared with the group 9 metals rhodium and iridium.

Table 4. Optimized $\mathrm{Cp}_{2} \mathrm{Re}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures within $10 \mathrm{kcal} / \mathrm{mol}$ of the global minimum and the global minimum $\mathrm{Cp}_{2} \mathrm{Ta}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structure lying $\sim 24 \mathrm{kcal} / \mathrm{mol}$ in energy below the next lowest energy structure.

## 3.5 $\left.\mathbf{C p}_{2} \mathbf{M}_{2} \mathbf{B}_{3} \mathbf{H}_{7} \mathbf{( M}=\mathbf{M o}, \mathbf{W}\right)$ structures.

Five of the six lowest energy $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Mo}, \mathrm{W})$ structures have central $\mathrm{M}_{2} \mathrm{~B}_{3}$ trigonal bipyramids with the metal atoms at two of the equatorial vertices (Figure 7 and Table 5). Four of these five trigonal bipyramidal structures, namely Mo2B3-1/W2B3-2, M2B3-3, M2B3-5, and M2B3-6 (M = Mo, W) have short M=M distances of $\sim 2.5 \AA$ with correspondingly high WBIs ranging from 1.36 to 1.53 . These can be interpreted as surface formal triple bonds. In all of these structures one of the "extra" hydrogen atoms bridges the $\mathrm{M} \equiv \mathrm{M}$ triple bond. The extra four electrons from these formal $\mathrm{M} \equiv \mathrm{M}$ triple bonds combined with the two electrons from each BH vertex, the four electrons from the "extra" four hydrogen atoms, and the single electron taken away by each -1 electron "donor" (i.e., electron acceptor) CpM vertex make these trigonal bipyramidal $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Mo}, \mathrm{W})$ structures 12 skeletal electron systems in accord with the Wade-Mingos rules. ${ }^{6,7,8}$ These four structures differ in the arrangement of the bridging hydrogen atoms. The other trigonal bipyramidal $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures M2B3-4 ( $\mathrm{M}=\mathrm{Mo}, \mathrm{W}$ ) have significantly longer M-M distances of $\sim 2.8 \AA$ with lower WBIs of
~1.0. The remaining low energy structures Mo2B3-2/W2B3-1 $(M=M o, W)$ have a central $\mathrm{M}_{2} \mathrm{~B}_{2}$ tetrahedron bridged on the $\mathrm{M}-\mathrm{M}$ edge with the third boron atom similar to the four $\mathrm{Cp}_{2} \mathrm{Re}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures Re2B3-1, Re2B3-2, Re2B3-6, and Re2B3-7 (Figure 6) and the $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Ru}$, Os) structures M2B3-3 (Figure 5). The structures Mo2B3-2/W2B3-1 ( $\mathrm{M}=\mathrm{Mo}, \mathrm{W}$ ) can be derived from the prevalent trigonal bipyramid isomers by breaking an axial-equatorial edge.

Figure 7. The six $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Mo}, \mathrm{W})$ structures within $10 \mathrm{kcal} / \mathrm{mol}$ of the global minima.

Table 5. The six optimized $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Mo}, \mathrm{W})$ structures within $10 \mathrm{kcal} / \mathrm{mol}$ of the global minima with relative energies in $\mathrm{kcal} / \mathrm{mol}$.

### 3.6 The single low-energy $\mathrm{Cp}_{2} \mathrm{Ta}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structure.

The $\mathrm{Cp}_{2} \mathrm{Ta}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ energy surface is surprisingly simple with a single structure Ta2B3-1 lying $\sim 24 \mathrm{kcal} / \mathrm{mol}$ below the next lowest energy structure (Figure 8 and Table 4). This structure has a central $\mathrm{Ta}_{2} \mathrm{~B}_{3}$ trigonal bipyramid with the tantalum atoms in equatorial positions. The $\mathrm{Ta}=\mathrm{Ta}$ distance of $2.737 \AA$ coupled with a WBI of 1.11 suggests a formal double or triple bond. Interpreting this $\mathrm{Ta}=\mathrm{Ta}$ interaction as a formal double bond and giving each tantalum atom a 16-electron configuration commonly found in early transition metal organometallics gives Ta2B3-1 a total of 12 skeletal electrons consistent with its trigonal bipyramidal geometry.

Figure 8. The single $\mathrm{Cp}_{2} \mathrm{Ta}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structure lying $\sim 24 \mathrm{kcal} / \mathrm{mol}$ in energy below the next lowest energy structure.

## 4. Summary

The predicted low-energy structures for $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Rh}$, Ir $)$ are tetragonal pyramids similar to the experimentally known ${ }^{29} \mathrm{Cp}^{*}{ }_{2} \mathrm{Rh}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ and the valence isoelectronic stable pentaborane- $9 \mathrm{~B}_{5} \mathrm{H}_{9}$ and consistent with their 14 Wadean skeletal electrons. Two $\mathrm{Cp}^{*}{ }_{2} \mathrm{Rh}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures with the same central $\mathrm{Rh}_{2} \mathrm{~B}_{3}$ tetragonal prism are found with energies within $\sim 1 \mathrm{kcal} / \mathrm{mol}$ of each other consistent with the experimental observation of two isomers in solution. The electron-richer $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Pd}, \mathrm{Pt})$ systems with 16 Wadean skeletal electrons are predicted to exhibit more open structures analogous to the known structure ${ }^{3}$ for the valence isoelectronic pentaborane- $11 \mathrm{~B}_{5} \mathrm{H}_{11}$.

Trigonal bipyramids with the metal atoms at equatorial vertices are typically found as low-energy structures for the hypoelectronic $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Ru}, \mathrm{Os})$ systems. For the lowest energy such trigonal bipyramidal $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures the metal-metal bonds are surface single bonds similar to the metal-metal bonds in the electron-richer
$\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Pd}, \mathrm{Pt} ; \mathrm{Rh}, \mathrm{Ir})$. This provides the expected 12 skeletal electrons for trigonal bipyramidal geometry. Five of the six lowest-energy structures of the electronpoorer $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Mo}, \mathrm{W})$ are also similar trigonal bipyramids with the metals in equatorial positions. However, in this case the $\mathrm{M} \equiv \mathrm{M}$ edges are unusually short with high Wiberg Bond Indices suggesting surface formal triple bonds. The extra skeletal electrons effectively provided by these triple bonds give these species the 12 skeletal electrons expected for a trigonal bipyramid. The single low-energy $\mathrm{Cp}_{2} \mathrm{Ta}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structure is also a similar trigonal bipyramid.

The low-energy structures of the rhenium derivatives $\mathrm{Cp}_{2} \mathrm{Re}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ provide examples of another type of structure based on a central $\mathrm{Re}_{2} \mathrm{~B}_{2}$ tetrahedron with the Re-Re edge bridged by the third boron atom. Such structures can be derived from a trigonal bipyramid by rupture of one of the axial-equatorial edges. Alternatively, such structures can be formulated as $\mathrm{Cp}_{2} \mathrm{Re}_{2}\left(\mu-\mathrm{BH}_{2}\right)\left(\mu-\mathrm{B}_{2} \mathrm{H}_{5}\right)$ with the $\mathrm{Re}-\mathrm{Re}$ bond bridged by both $\mathrm{BH}_{2}$ and $\mathrm{B}_{2} \mathrm{H}_{5}$ ligands.

## Graphical Abstract

Dimetallaborane Analogues The lowest energy $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}(\mathrm{M}=\mathrm{Pd}, \mathrm{Pt})$ of Pentaborane

Adrian M. V. Brânzanic, Alexandru

Lupan,* and R. Bruce King*
analogous to the isoelectronic $\mathrm{B}_{5} \mathrm{H}_{11}$ and $\mathrm{B}_{5} \mathrm{H}_{9}$, respectively. Trigonal bipyramidal structures are found for the electron poorer $\mathrm{Cp}_{2} \mathrm{M}_{2} \mathrm{~B}_{3} \mathrm{H}_{7} \quad(\mathrm{M}=\mathrm{Ru}, \mathrm{Os}, \mathrm{Mo}, \mathrm{W}, \mathrm{Ta})$ systems. Low energy $\mathrm{Cp}_{2} \mathrm{Re}_{2} \mathrm{~B}_{3} \mathrm{H}_{7}$ structures include $\mathrm{Re}_{2} \mathrm{~B}_{2}$ tetrahedra with the Re-Re edge capped by the third boron atom.

[^0]:    ${ }^{\dagger}$ This paper is dedicated to the memory of the late Prof. Kenneth Wade in recognition of his seminal contributions to the understanding of the structure and bonding in polyhedral boranes and related clusters.
