Accepted Manuscript

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this *Accepted Manuscript* with the edited and formatted *Advance Article* as soon as it is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

ARTICLE

Synthesis and Lewis Acidity of Fluorophosphonium Cations

A series of fluorophosphonium salts, $[R_3PF][X]$ (R = alkyl or aryl; X = $FB(C_6F_5)_3$, $[B(C_6F_5)_4]$), have been prepared by reactions of phosphine / borane frustrated Lewis pairs (FLPs) with XeF_2 or difluorophosphoranes with $[Et_3Si][B(C_6F_5)_4]$. As the substituents bound to phosphorus become increasingly electron withdrawing, the corresponding fluorophosphonium salts are shown to be increasingly Lewis acidic. Calculations were also performed to determine the relative fluoride ion affinities (FIA) of these fluorophosphonium cations.

The p-block elements which have been exploited for their Lewis acidic properties have thus far mainly consisted of boron,¹ aluminium,² and silicon,³ although heavier elements have also been investigated to a lesser extent.⁴ Such group 13 and 14 electrophiles have found utility in a range of Lewis acid chemistry and catalysis⁵⁻⁸ as well as in the domain of frustrated Lewis pair (FLP) chemistry.¹ In contrast, group 15 compounds have mainly been exploited for their Lewis basic properties and thus as σ -donor for applications in transition metal coordination, organometallic chemistry and catalysis.⁹⁻¹³ An overlooked subset of phosphorus chemistry is the ability for these compounds to act as acceptors. Phosphonium or P(III) cations contain both a lone pair of electrons and an empty p-orbital. Such systems have been shown to exhibit nucleophilic and electrophilic character acting as both donors and acceptors.¹⁴⁻²² In a recent result we have described the direct reaction of a triphosphabenzene derivative with H_2 .²³ In this case, computational work supports an FLP-type mechanism in which P and C acts as Lewis acidic and Lewis basic centers respectively in the heterolytic cleavage of H_2 .

The electrophilicity of higher oxidation state phosphorus-species have also been exploited in the classic Wittig²⁴ and Staudinger²⁵ reactions. In addition, phosphonium Lewis acids have been employed in catalytic transformation, including Diels-Alder cyclization reactions,²⁶ addition reactions to polar unsaturates,²⁷ and as sensors for fluoride ions.²⁸ More recently, we have utilized electron withdrawing fluorine and pentafluorophenyl substituents to develop highly electrophilic fluorophosphonium cations. These cations have been shown to be highly effective Lewis acids for the stoichiometric sequestration of carbon dioxide,²⁹ as well as the catalytic hydrodefluorination of fluoroalkanes,³⁰ hydrosilylation of olefins and alkynes,³¹ dehydrocoupling of amines, alcohols,

acids and thiols with silanes as well as tandem transfer hydrogenation of olefins (Scheme 1).³²

Scheme 1 Reactions of Electrophilic phosphonium cations.

In this full report we described the facile synthesis and full characterization of a series of fluorophosphonium salts. In an effort to rank these Lewis acids with known systems, various approaches to Lewis acidity evaluation are considered and discussed.

Experimental section

General procedures: All preparations and manipulations were carried out under an anhydrous N_2 atmosphere using standard Schlenk and glovebox techniques. All glassware was oven-dried and cooled under vacuum before use. Commercial reagents were purchased from Sigma-Aldrich, Strem Chemicals or Apollo Scientific, and were used without further purification unless indicated otherwise. CH_2Cl_2 , Et_2O ,

n-pentane, and toluene were dried using an Innovative Technologies solvent purification system. CD₂Cl₂ and CDCl₃ (Aldrich) were deoxygenated, distilled over CaH₂, then stored over 4 Å molecular sieves before use. C₆D₅Br (Aldrich) was deoxygenated and stored over 4 Å molecular sieves before use. NMR spectra were obtained on a Bruker AvanceIII-400 MHz spectrometer. ¹H NMR data, referenced to external Me₄Si, are reported as follows: chemical shift (δ / ppm), coupling constant (Hz), normalized integrals. ¹³C{¹H} NMR chemical shifts (δ / ppm) are referenced to external Me₄Si. [Ph₂(C₆F₅)PF][FB(C₆F₅)₃] (**6**), [Ph(C₆F₅)₂PF][B(C₆F₅)₄] (**7**), and [(C₆F₅)₃PF][B(C₆F₅)₄] (**8**), were prepared by the reported procedures.^{30, 33} F₂PR₃ (R = *t*Bu³⁴, Mes³⁵, *o*-Tol³⁵, Ph³⁶, *p*-C₆H₄F³⁷) are literature known but were synthesized by different routes. NMR spectroscopic data match with the literature values.

Synthesis of [^tBu₃PF][FB(C₆F₅)₃] (1**)** Two procedures can be utilized to synthesize this product the first involving addition of XeF₂ to the FLP and the second involving initial phosphine oxidation followed by borane abstraction of fluoride. Both are described below. (1) A solution of *t*Bu₃P (40 mg, 195 μmol) in 5 mL of dichloromethane was added to B(C₆F₅)₃ (100 mg, 195 μmol). This solution was added to XeF₂ (33 mg, 195 μmol) in 5 mL of dichloromethane, resulting in immediate effervescence. The reaction was allowed to stir for 10 minutes and the solvent was removed *in vacuo* producing a colorless solid that was washed with pentane (3 x 2 mL) and was dried *in vacuo*. (2) A solution of *t*Bu₃P (40 mg, 195 μmol) in 5 mL of dichloromethane was added to a solution of XeF₂ (33 mg, 195 μmol) in 5 mL of dichloromethane, resulting in immediate effervescence. When effervescence had ceased (~ 1 minute), the colourless solution was allowed to stir for an additional 5 minutes. B(C₆F₅)₃ (100 mg, 195 μmol) was added and the solvent was removed *in vacuo* producing a colorless solid that was washed with pentane (3 x 2 mL) and was dried *in vacuo*. Diffraction quality crystals were grown from a saturated solution of dichloromethane and *n*-pentane (139 mg, 95%, Anal. Calcd. for C₃₀H₂₇BF₁₇P: C, 47.90; H, 3.62%. Found C, 47.78; H, 3.73%). ¹H NMR (CD₂Cl₂, 400 MHz, Me₄Si): δ 1.63 (dd, ³J_{PH} = 15.9 Hz, ⁴J_{FH} = 1.4 Hz, 27H, CH₃). ¹¹B NMR (CD₂Cl₂, 128 MHz, BF₃·OEt₂): δ -0.6 (d, ¹J_{FB} = 70 Hz, BF). ¹⁹F NMR (CD₂Cl₂, 377 MHz, CFCl₃): δ -136.6 (m, 6F, *o*-C₆F₅), -162.7 (t, ³J_{FF} = 20 Hz, 3F *p*-C₆F₅), -167.0 (m, 6F, *m*-C₆F₅), -171.6 (d, ¹J_{PF} = 1019 Hz, 1F, PF), -190.3 (q/br, ¹J_{FB} = 70 Hz, 1F, BF). ³¹P{¹H} NMR (CD₂Cl₂, 162 MHz, H₃PO₄): δ 148.5 (d, ¹J_{PF} = 1019 Hz, PF). ¹³C{¹H} NMR (CD₂Cl₂, 100 MHz, Me₄Si): δ 148.2 (dm, ¹J_{FC} = 240 Hz, 6C, C₆F₅), 139.1 (dm, ¹J_{FC} = 206 Hz, 3C, *p*-C₆F₅), 136.8 (dm, ¹J_{FC} = 231 Hz, 6C, C₆F₅), 41.4 (dd, ¹J_{PC} = 26 Hz, ²J_{FC} = 7 Hz, 3C, C(CH₃)₃), 27.9 (dd, ²J_{PC} = 2 Hz, ³J_{FC} = 1 Hz, 9C, C(CH₃)₃), not observed *i*-C₆F₅.

Synthesis of [Mes₃PF][FB(C₆F₅)₃] (2**)** The compound was prepared in a manner similar to that of **1** using Mes₃P (76 mg, 195 μmol), XeF₂ (33 mg, 195 μmol), B(C₆F₅)₃ (100 mg, 195 μmol), and was isolated as a white solid (153 mg, 163 μmol, 84% yield). Anal. Calcd. for C₄₅H₃₃BF₁₇P: C, 57.59; H, 3.54%. Found: C, 57.54; H, 3.76%. ¹H NMR (CD₂Cl₂, 400 MHz, Me₄Si): δ 7.22 (d, ⁴J_{PH} = 3.8 Hz, 3H, *m*-Mes), 7.08 (d, ⁴J_{PH} = 6.6 Hz, 3H, *m*-Mes), 2.41 (s, 9H, *o*-CH₃), 2.34 (d, ⁴J_{PH} = 6.1 Hz, 9H, *o*-CH₃), 1.96 (s, 9H, *p*-CH₃). ¹¹B NMR (CD₂Cl₂, 128 MHz, BF₃·OEt₂): δ -0.6 (d, ¹J_{FB} = 69 Hz, BF). ¹⁹F NMR

(CD₂Cl₂, 377 MHz, CFCl₃): δ -116.7 (d, ¹J_{PF} = 940 Hz, 1F, PF), -136.6 (m, 6F, *o*-C₆F₅), -163.7 (t, ³J_{FF} = 20 Hz, 3F *p*-C₆F₅), -168.0 (m, 6F, *m*-C₆F₅), -190.9 (q/br, ¹J_{FB} = 69 Hz, 1F, BF). ³¹P{¹H} NMR (CD₂Cl₂, 162 MHz, H₃PO₄): δ 92.9 (d, ¹J_{PF} = 940 Hz, PF). ¹³C{¹H} NMR (CD₂Cl₂, 100 MHz, Me₄Si): δ 149.4 (dd, ¹J_{PC} = 3 Hz, ¹J_{FC} = 1 Hz, 3C, Mes), 148.3 (dm, ¹J_{FC} = 240 Hz, 6C, C₆F₅), 145.5 (dd, ¹J_{PC} = 8 Hz, ¹J_{FC} = 1 Hz, 3C, Mes), 144.0 (dd, ¹J_{PC} = 18 Hz, ¹J_{FC} = 3 Hz, 3C, Mes), 139.1 (dm, ¹J_{FC} = 206 Hz, 3C, *p*-C₆F₅), 136.8 (dm, ¹J_{FC} = 231 Hz, 6C, C₆F₅), 133.5 (d, ¹J_{PC} = 14 Hz, 3C, Mes), 133.5 (d, 11 Hz, 3C, Mes), 117.1 (dd, ¹J_{PC} = 99 Hz, ²J_{FC} = 13 Hz, 3C, *i*-Mes), 23.3 (d, ³J_{PC} = 6 Hz, 3C, *o*-Me), 22.5 (dd, ¹J_{FC} = 7 Hz, ¹J_{PC} = 5 Hz, 3C, *o*-Me), 21.7 (s, 3C, *p*-Me), not observed *i*-C₆F₅.

Synthesis of [(*o*-Tol)₃PF][FB(C₆F₅)₃] (3**)** The compound was prepared in a manner similar to that of **1** using (*o*-Tol)₃P (59 mg, 195 μmol), XeF₂ (33 mg, 195 μmol), B(C₆F₅)₃ (100 mg, 195 μmol), and was isolated as a white solid (151 mg, 130 μmol, 91%). Anal. Calcd. for C₃₉H₂₁BF₁₇P: C, 54.83; H, 2.48%. Found: C, 54.26; H, 2.46%. ¹H NMR (CD₂Cl₂, 400 MHz, Me₄Si): δ 7.92 (m, 3H, Tol), 7.68 (m, 3H, Tol), 7.51 (m, 3H, Tol), 7.22 (m, 3H, Tol), 2.47 (d, ³J_{HH} = 2.6 Hz, 9H, CH₃). ¹¹B NMR (CD₂Cl₂, 128 MHz, BF₃·OEt₂): δ -0.6 (d/br, ¹J_{FB} = 70 Hz, BF). ¹⁹F NMR (CD₂Cl₂, 377 MHz, CFCl₃): δ -125.5 (d, ¹J_{PF} = 994 Hz, 1F, PF), -135.6 (m, 6F, *o*-C₆F₅), -162.7 (t, ³J_{FF} = 21 Hz, 3F *p*-C₆F₅), -167.0 (m, 6F, *m*-C₆F₅), -190.9 (s/br, 1F, BF). ³¹P{¹H} NMR (CD₂Cl₂, 162 MHz, H₃PO₄): δ 104.3 (d, ¹J_{PF} = 994 Hz, PF). ¹³C{¹H} NMR (CD₂Cl₂, 100 MHz, Me₄Si): δ 148.2 (dm, ¹J_{FC} = 240 Hz, 6C, C₆F₅), 145.4 (dd, ¹J_{PC} = 9 Hz, ¹J_{FC} = 1 Hz, 3C, Tol), 139.2 (dm, ¹J_{FC} = 206 Hz, 3C *p*-C₆F₅), 138.8 (dd, ¹J_{PC} = 3 Hz, ¹J_{FC} = 1 Hz, 3C, Tol), 136.9 (dm, ¹J_{FC} = 231 Hz, 6C, C₆F₅), 135.6 (dd, ¹J_{PC} = 18 Hz, ¹J_{FC} = 2 Hz, 3C, Tol), 134.4 (d, ¹J_{PC} = 12 Hz, 3C, Tol), 128.3 (d, ¹J_{PC} = 16 Hz, 3C, Tol), 115.7 (dd, ¹J_{PC} = 105 Hz, ²J_{FC} = 13 Hz, 3C, *i*-Tol), 22.0 (dd, ³J_{PC} = Hz, ⁴J_{FC} = Hz, 3C, *o*-Me), not observed *i*-C₆F₅.

Synthesis of [Ph₃PF][FB(C₆F₅)₃] (4**)** The compound was prepared in a manner similar to that of **1** using Ph₃P (51 mg, 195 μmol), XeF₂ (33 mg, 195 μmol), B(C₆F₅)₃ (100 mg, 195 μmol), and was isolated as a white solid (157 mg, 193 μmol, 99%). Anal. Calcd. for C₃₆H₁₅BF₁₇P: C, 53.23; H, 1.86%. Found: C, 52.80; H, 1.71%. ¹H NMR (CD₂Cl₂, 400 MHz, Me₄Si): δ 8.04 (m, 3H, Ph), 7.85 - 7.74 (12H, Ph). ¹¹B NMR (CD₂Cl₂, 128 MHz, BF₃·OEt₂): δ -0.6 (d/br, ¹J_{FB} = 57 Hz, BF). ¹⁹F NMR (CD₂Cl₂, CFCl₃, 377 MHz): δ -128.3 (d, ¹J_{PF} = 996 Hz, 1F, PF), -135.6 (d, ³J_{FF} = 20 Hz, 6F, *o*-C₆F₅), -162.4 (t, ³J_{FF} = 19 Hz, 3F, *p*-C₆F₅), -166.9 (m, 6F, *m*-C₆F₅), -190.9 (s/br, 1F, BF). ³¹P{¹H} NMR (CD₂Cl₂, 162 MHz, H₃PO₄): δ 94.7 (d, ¹J_{PF} = 996 Hz, PF). ¹³C{¹H} NMR (CD₂Cl₂, 100 MHz, Me₄Si): δ 148.4 (dm, ¹J_{FC} = 240 Hz, 6C, C₆F₅), 139.2 (dm, ¹J_{FC} = 206 Hz, 3C *p*-C₆F₅), 138.9 (dd, ⁴J_{PC} = 3 Hz, ⁵J_{FC} = 2 Hz, 3C, *p*-Ph), 136.9 (dm, ¹J_{FC} = 231 Hz, 6C, C₆F₅), 134.3 (dd, ¹J_{PC} = 13 Hz, ¹J_{FC} = 1 Hz, 6C, Ph), 131.2 (d, ¹J_{PC} = 14 Hz, 6C, Ph), 116.5 (dd, ¹J_{PC} = 109 Hz, ²J_{FC} = 15 Hz, 3C, *i*-Ph), not observed *i*-C₆F₅.

Synthesis of [(*p*-C₆H₄F)₃PF][FB(C₆F₅)₃] (5**)** The compound was prepared in a manner similar to that of **5** using (*p*-C₆H₄F)₃P (62 mg, 195 μmol), XeF₂ (33 mg, 195 μmol), B(C₆F₅)₃ (100 mg, 195 μmol), and was isolated as a white solid (149 mg, 172 μmol, 88%). Anal. Calcd. for C₃₆H₁₂BF₂₀P: C, 49.92; H, 1.40%. Found: C, 49.36; H, 1.60%. ¹H NMR (CD₂Cl₂, 400 MHz, Me₄Si): δ 7.84 (m, 6H, C₆H₄F),

7.48 (m, 6H, C₆H₄F). ¹¹B NMR (CD₂Cl₂, 128 MHz, BF₃·OEt₂): δ = 0.6 (d/br, ¹J_{FB} = 62 Hz, BF). ¹⁹F NMR (CD₂Cl₂, 377 MHz, CFCl₃): δ = -93.9 (s, 3F, C₆H₄F), -123.8 (d, ¹J_{PF} = 994 Hz, 1F, PF), -135.6 (d, ³J_{FF} = 20 Hz, 6F, *o*-C₆F₅), -162.4 (t, ³J_{FF} = 19 Hz, 3F, *p*-C₆F₅), -166.9 (m, 6F, *m*-C₆F₅), -190.9 (s/br, 1F, BF). ³¹P{¹H} NMR (CD₂Cl₂, 162 MHz, H₃PO₄): δ = 93.3 (d, ¹J_{PF} = 998 Hz, PF). ¹³C{¹H} NMR not obtained due to insolubility.

Synthesis of (*p*-C₆F₄H)₃P *i*-PrMgCl (10.9 mL, 21.8 mmol, 2 M) was added to a solution of *p*-C₆F₄HBr (5.00 g, 21.8 mmol) in Et₂O (100 mL) and stirred for 1 hour at ambient temperature. To the cloudy solution was added copper(I) iodide (416 mg, 2.2 mmol) and a solution of PCl₃ (1.00 g, 7.3 mmol) in Et₂O (5 mL). The suspension was stirred for an additional 2h and filtered. The residue was washed with 10 mL Et₂O and the solvent was removed from the collected extracts *in vacuo* to give a colorless solid as the crude product. Recrystallization from hexane yield the product as crystalline, colorless solid. Yield: 3.30 g (94%). NMR spectroscopic data match previously reported.³⁸ ¹H NMR (499.7 MHz, CD₂Cl₂, Me₄Si): δ = 7.25 ppm (m, CH); ¹³C{¹H} NMR (125.7 MHz, CD₂Cl₂, Me₄Si): δ = 147.3 (dm, ¹J_{CF} = 248 Hz), 145.9 (dm, ¹J_{CF} = 249 Hz), 111.3–110.7 (m, *i*-C), 108.9 ppm (t, ²J_{CF} = 22.8 Hz, CH); ¹⁹F NMR (376.6 MHz, CD₂Cl₂, CFCl₃): δ = -131.2 (m, 6F, *o*-C₆F₄H), -138.2 ppm (m, 6F, *m*-C₆F₄H); ³¹P{¹H} NMR (162.0 MHz, CD₂Cl₂, H₃PO₄): δ = -72.3 ppm (sept, ³J_{PF} = 36.4 Hz).

Synthesis of R₃PF₂ (R = *t*Bu (9), Mes (10), *o*-Tol (11), Ph (12), *p*-C₆H₄F (13), *p*-C₆H₄F (14)) To a solution of R₃P (262.3 mg, 1.0 mmol) in CH₂Cl₂ (10 mL) was added a solution of XeF₂ (169.3 mg, 1.0 mmol) in CH₂Cl₂ (10 mL). After 1 hour at ambient temperature the solvent was removed *in vacuo* and the remaining solid was washed with *n*-pentane (5 mL). The solid was dried *in vacuo* yielding the product as a colorless powder in quantitatively yield.

X-ray Data Collection, Reduction, Solution and Refinement

Single crystals were coated in Paratone-N oil in the glove-box, mounted on a MiTegen Micromount and placed under an N_2 stream. The data were collected on a Bruker Apex II diffractometer. The data were collected at 150(\pm 2) K for all crystals. Data reduction was performed using the SAINT software package, and an absorption correction was applied using SADABS. The structures were solved by direct methods using XS and refined by full-matrix least squares on F^2 using XL as implemented in the SHELXTL suite of programs. All non-hydrogen atoms were refined anisotropically. Carbon-bound hydrogen atoms were placed in calculated positions using an appropriate riding model and coupled isotropic temperature factors.

Results and discussion

Synthesis: The careful addition of a CD_2Cl_2 solution containing 1 : 1 $tBu_3P / B(C_6F_5)_3$ to XeF_2 at ambient temperature immediately resulted in vigorous effervesce to produce the fluorophosphonium fluoroborate salt, $[tBu_3PF][B(C_6F_5)_3]$ (**1**; Scheme 1), which could be isolated in quantitative yield as a colourless, analytically pure solid. $^{31}P\{^1H\}$ NMR spectroscopy of the resulting mixture shows a doublet signal at δ 148.5 ppm ($^1J_{PF}$ = 1019 Hz), while the ^{19}F NMR spectrum shows the corresponding doublet resonance at δ -171.6 ppm, consistent with the formulation. The selective production of **1** suggests that the FLP reacts with XeF_2 by a mechanism involving phosphine oxidation and fluoride ion abstraction by $B(C_6F_5)_3$. The observed reactivity is in stark contrast to that of reaction of intramolecular P/B FLP systems with XeF_2 ³⁹ where complexation of the borane to $tBuNC$ was required to achieve clean oxidation to the corresponding fluorophosphonium fluoroborate.

The aforementioned reactivity was extended to a series of variously substituted organophosphine precursors, including Mes_3P , $(o-Tol)_3P$, Ph_3P and $(p-C_6H_4F)_3P$. In the presence of 1 equiv. of $B(C_6F_5)_3$, the resulting FLPs reacted with XeF_2 to yield salts of the

formula $[R_3PF][FB(C_6F_5)_3]$, where R = Mes (**2**), *o*-Tol (**3**), Ph (**4**), or *p*-C₆H₄F (**5**) (Scheme 2). NMR data for triarylphosphonium salts **2** and **3** each show significantly upfield-shifted ³¹P NMR resonances (δ 92.9 and 104.3, respectively), and downfield-shifted ¹⁹F signals (δ -116.7 and -125.5, respectively) relative to that of trialkylphosphonium salt **1**, which can be crystallized from a mixture of CH₂Cl₂ and *n*-pentane. X-ray structural analysis of **1** shows the expected tetrahedral geometry around both P and B centers (Figure 1). The P–F and B–F bond lengths are normal at 1.628(2) Å and 1.427(3) Å, respectively, and there appear to be no strong interactions between the cation and the anion.

Figure 1. POV-Ray depictions of compounds (a) **1** and (b) **3**. P: orange; F: pink; B: green; C: black.

A crystallographic analysis of **3** (Figure 1) also shows a typical B–F bond length of 1.418(6) Å, although its P–F bond length of 1.554(3) Å is substantially shorter than that in **1**. This difference is attributed to the more steric demands of the *t*Bu groups in **1** in comparison to the *ortho*-tolyl groups in **3** which more readily accommodates a pseudo tetrahedral geometry. This difference in the geometry at P is also illustrated by the sum of the C–P–C angles which is 344.4° in **1** and 337.2° in **3**. In addition, the P center in **3** is more electron deficient and thus accommodates a shorter P–F bond. Interestingly, compound **3** also seems to exhibit a weak cation-anion interaction, although the (B)F⋯P(F) separation of *ca.* 3.55 Å is greater than the sum of the van der Waals radii of these atoms (3.24 Å),⁴⁰ suggesting that favorable π -stacking and Coulombic interactions between these ions instead stabilize their mutual orientation in the solid state.

Scheme 2. Reaction of XeF₂ with phosphine / borane FLPs.

The reaction between Ph₃P / B(C₆F₅)₃ and XeF₂ is much slower proceeding over several days to gradually yield **4** as the product. Such sluggish reactivity is attributable to the competing reaction in which Ph₃P forms an adduct with B(C₆F₅)₃ at ambient temperature. Nevertheless, the dissociation equilibrium of Ph₃P–B(C₆F₅)₃ in solution allows for gradual oxidation of free Ph₃P to the unobserved intermediate difluorophosphorane, Ph₃PF₂, which immediately undergoes fluoride abstraction by B(C₆F₅)₃ to yield [Ph₃PF][B(C₆F₅)₃] (**4**). Supporting this mechanistic interpretation is the observation that combining Ph₃P and XeF₂ in solution without B(C₆F₅)₃ results in immediate effervescence, and subsequent addition of B(C₆F₅)₃ yields (**4**) in a matter of minutes. It is also interesting to note that in a recent investigation in collaboration with the Erker group,³⁹ we described the reactions of intramolecular FLPs with XeF₂. These reactions proceed in a similar fashion to those with other halogenating reagents.⁴¹

With the exception of Ph₃P, the apparent rate of reactions between XeF₂ and phosphine / B(C₆F₅)₃ FLPs are noticeably reduced as increasingly electron-withdrawing substituents are appended to P. Our previous report describing the reaction between XeF₂ and the electron-deficient phosphine / borane combination, Ph₂(C₆F₅)P / B(C₆F₅)₃, demonstrated the anticipated formation of salt **6**. Interestingly however, **6** was found to exist in equilibrium with free B(C₆F₅)₃ and the difluorophosphorane, Ph₂(C₆F₅)PF₂, by rapid fluoride ion transfer between P and B centers, made evident by variable temperature ³¹P{¹H} and ¹⁹F NMR spectroscopy.³³ Analogous reactions using the phosphines Ph(C₆F₅)₂P, (*p*-C₆H₄H)₃P³⁸ and (C₆F₅)₃P also result in their oxidation to the difluorophosphorane. In these cases however, B(C₆F₅)₃ does not abstract fluoride from the corresponding difluorophosphoranes, indicating that the targeted fluorophosphonium cations are more Lewis acidic than B(C₆F₅)₃ towards fluoride. Nonetheless, fluoride ion abstraction from the difluorophosphoranes can be achieved employing the harder electrophiles such as Al(C₆F₅)₃ or [Et₃Si][B(C₆F₅)₄]. We have previously utilized this technique to access highly electrophilic fluorophosphonium cations, [(C₆F₅)₂PhPF]⁺ (**7**) and [(C₆F₅)₃PF]⁺ (**8**), which have shown a wide range of reactivity (*vide supra*).

This synthetic approach was subsequently applied to all previously synthesized phosphonium cations to eliminate the non-innocent [FB(C₆F₅)₃][−] anion. Thus, initial oxidation of the phosphines with XeF₂ yields the difluorophosphoranes R'R₂PF₂, [R, R' = *t*Bu (**9**), Mes (**10**), *o*-Tol (**11**), Ph (**12**), *p*-C₆H₄F (**13**), and *p*-C₆F₄H (**14**), R = Ph, R' = C₆F₅ (**15**)] in quantitatively yields. Subsequently fluoride abstraction of the difluorophosphoranes with [Et₃Si][B(C₆F₅)₄] yield the salts of the formula [R'R₂PF][B(C₆F₅)₄], where R, R' = *t*Bu (**16**), Mes (**17**), *o*-Tol (**18**), Ph (**19**), *p*-C₆H₄F (**20**), and *p*-C₆F₄H (**21**), R =

Ph, R' = C₆F₅ (**22**) (Scheme 3). NMR data for **9–15** were consistent with the formulations while the data for the cations of compounds **16–20** are consistent with that described for **1–5**. In each of **16–22**, the [B(C₆F₅)₄] anion give rise to signals in the ¹¹B and ¹⁹F NMR spectra at δ -16.7 and -133.0 (*o*-C₆F₅), -163.7 (*p*-C₆F₅) and -167.8 (*m*-C₆F₅), respectively.

Figure 2. POV-Ray depictions of the cations of (a) **17** (b) **19**, (c) **20**, (d) **21**, (e) **22**. Hydrogen atoms are omitted for clarity. P: orange; F: pink; B: green; C: black.

Crystals suitable for X-ray crystallographic studies of compound **17**, **19**, **20**, **21** and **22** were obtained from a concentrated CH₂Cl₂ solution at -35 °C (Figure 2). The P–F bond lengths of the Mes (**17**), Ph (**19**), *p*-C₆H₄F (**20**) *p*-C₆F₄H (**21**) and Ph₂(C₆F₅) (**22**) substituted fluorophosphonium cations were found to be 1.561(1), 1.556(2),

1.553(1), 1.527(4) Å and 1.540(3) Å, respectively. The shortest P–F distances is consistent with the presence of the most electron withdrawing *p*-C₆F₄H substituents in **21**. This value is similar to that see for the P–F bond length in [(C₆F₅)₂PhPF][F(Al(C₆F₅)₃)₂] with 1.533(2) Å.³⁰ The sum of the C–P–C angles for the more sterically encumbered phosphonium cation **17** has values of 344.3°. With decreasing bulkiness around the phosphorus atom the sum of C–P–C angles adopt smaller values of 339.7° in **19**, 336.3° in **20**, 338.8° in **21** and 336.2° in **22**, respectively. In all structures the parameters of the anion [B(C₆F₅)₄] are unexceptional.

Scheme 3. Synthesis of fluorophosphonium salts.

It is interesting to note some trends observed in the spectroscopic data of the fluorophosphonium cations. For the series of fluorophosphonium cations the ³¹P{¹H} NMR chemical shift decreases with increasingly electron-withdrawing substituents (Figure 3). Conversely, ¹⁹F NMR chemical shifts attributable to the P-bound F atom generally increase with Lewis acidity. It is interesting that the mesityl- substituted derivative (**2**) does not strictly adhere to this trend. This discrepancy is perhaps best attributed to the impact of the increased steric crowding in this triarylphosphonium cation, which may affect shielding of the ³¹P and/or ¹⁹F nuclei. Nonetheless, these observations suggest that the ³¹P and ¹⁹F chemical shifts are correlated with the expected Lewis acidity of these fluorophosphonium cations.

Figure 3. Stack plot of the ³¹P{¹H} NMR data for a series of fluorophosphonium cations.

To further probe the Lewis acidity of these phosphonium cations efforts were made to employ standardized methods employed to rank these Lewis acids. Initially efforts to use the Child's test⁴² proved unsuccessful as the combination of crotonaldehyde with fluorophosphonium salts resulted in the formation of a complex

mixture of products. Employing the Gutmann-Beckett protocol,⁴³⁻⁴⁴ addition of one equivalent of Et₃PO to the least Lewis acidic compounds among the series, **1**, **2** or **3** resulted in no observable change in the ³¹P NMR chemical shifts indicative of no interaction of the phosphine-oxide with these Lewis acids. In contrast, addition of Et₃PO to the more electron-deficient salt **4** led to the generation of the difluorophosphorane, Ph₃PF₂ and the adduct (Et₃PO)B(C₆F₅)₃. This observation confirms fluoride ion transfer from B to P with concurrent sequestration of the phosphine-oxide by the freed borane (Scheme 4). A similar result was previously observed with the more Lewis acidic salt **6**.³³ Interestingly combination of **19** where the [B(C₆F₅)₄] counterion circumvents the reaction of phosphine-oxide with the anion, no interaction of the cation with Et₃PO was evident from the ³¹P NMR spectroscopy. We have previously reported that Et₃PO coordinates to the cation of **8** affording a shift of the ³¹P signal for the phosphine oxide to 91.1 ppm and thus a Gutmann-Beckett Δδ of 40.4.³⁰ The combination of the tetrafluorophenyl-substituted fluorophosphonium (**21**) with Et₃PO in CD₂Cl₂ gave rise of a signal for the coordinated phosphine oxide at 89.5 ppm in the ³¹P NMR spectrum and thus Δδ of 38.8. This suggests that **21** is about 5% less Lewis acidic than [(C₆F₅)₃PF][B(C₆F₅)₄]. This situation is analogous to the Lewis acidities of B(*p*-C₆F₄H)₃ and B(C₆F₅)₃.⁴⁵ Nonetheless, the present results indicate that both the Child's and Gutmann-Beckett methods have limited utility in efforts to establish a ranking of the Lewis acidities of fluorophosphonium cations with other known Lewis acids.

Scheme 4. Reactions of **6** and **19** with Et₃PO.

An alternative strategy to assess Lewis acidity to these experimental methods, is a method developed by Bartlett,⁴⁶ in which the fluoride ion affinity (FIA) is computed. The Crossing group used this approach to determine the relative Lewis acidities for a number of neutral Lewis acids.⁴⁷⁻⁴⁸ In addition, Slattery *et al.* have calculated the FIA of a number of free phosphonium cations and the results show that certain free phosphonium cations have the potential to be as Lewis acidic as silylium cations.⁴⁹ In this method two computational approaches were used. The first involved the calculation of enthalpy (ΔH) using WB97XD/def2TZV level of theory⁵⁰⁻⁵¹ in conjunction with the conductor-like polarizable continuum solvation model (CPCM)⁵²⁻⁵⁵ in dichloromethane for the reaction of F⁻ with [R₃PF]⁺ forming the corresponding difluorophosphorane (Eq'n 1). The FIA is then defined as the negative of the enthalpy ΔH.^{46, 56-57} The second approach utilized a gas phase pseudo-isodesmic reaction between the fluorophosphonium cations and [COF₃]⁻ acting as F⁻ donor forming corresponding difluorophosphorane and COF₂. These latter calculations are anchored to an experimental ΔH value of the addition of F⁻ to COF₂ forming [COF₃]⁻ of 209 kJ/mol.^{49, 56} In addition, the ³¹P NMR chemical shifts the phosphonium cations were calculated using gauge-including atomic orbital method (GIAO)⁵⁸⁻⁵⁹ at

WB97XD/def2TZV level of theory (Table 1). The calculated ³¹P NMR chemical shifts were referenced to chemical shift of [Me₃PF]⁺, and although there is some divergence from the experimental observations the computed shifts follow the same trends.

Table 1. NMR data and FIA for fluorophosphonium cations.

Cation	³¹ P	¹⁹ F	³¹ P _{calc}	FIA (F ⁻)	FIA (COF ₃) ⁻
[tBu ₃ PF] ⁺	148.5	-171.6	181.6	163	148
[Mes ₃ PF] ⁺	92.9	-116.7	-	-	-
[o-tol ₃ PF] ⁺	104.3	-125.5	-	-	-
[Ph ₃ PF] ⁺	94.7	-128.3	108.1	200	165
[(<i>p</i> -C ₆ H ₄ F) ₃ PF] ⁺	93.3	-123.8	103.7	220	214
[Ph ₂ (C ₆ F ₅)PF] ⁺	87.2	-123.4	90.9	238	227
[(C ₆ F ₅) ₂ PhPF] ⁺	77.7	-121.9	71.6	275	280
[(<i>p</i> -C ₆ H ₄ F) ₃ PF] ⁺	70.1	-124.4	-	296	287
[(C ₆ F ₅) ₃ PF] ⁺	68.0	-120.7	53.2	311	323

Interestingly the calculated FIA values are well correlated with implications of the observed ³¹P and ¹⁹F NMR chemical shifts for the fluorophosphonium cations. For example, the 5% difference in Lewis acidity between **21** and **8** inferred by the Gutmann-Beckett method is also predicted by the FIA calculations. Thus, stronger electron withdrawing substituents on P leads to higher FIA values consistent with greater Lewis acidity. Furthermore, the FIA of B(C₆F₅)₃ calculated at the same level of theory was found to be 260 kJ mol⁻¹, in good agreement with experimental observation that a fluoride anion can be abstracted by B(C₆F₅)₃ from the alkyl and aryl substituted difluorophosphoranes with FIA values lower than that of the B(C₆F₅)₃. At the same time this is also consistent with the observation that B(C₆F₅)₃ does not abstract fluoride from *bis*- and *tris*-pentafluorophenyl substituted difluorophosphoranes, where the FIA is computed to be higher than that of B(C₆F₅)₃.

Conclusions

The reaction of a variety of phosphine/borane FLPs with XeF₂ proceeds cleanly to afford the resulting fluorophosphonium fluoroborate salts. These fluorophosphonium cations become increasingly electrophilic as the substituents become more electron withdrawing. When there are two or more pentafluorophenyl substituents on the phosphine, B(C₆F₅)₃ is not a strong enough Lewis acid to abstract the fluoride; a notion that is supported by a comparison of the calculated FIAs. The aforementioned fluorophosphonium cations were also generated using [Et₃Si][B(C₆F₅)₄] in an effort to remove the non-innocent [FB(C₆F₅)₃]⁻ anion. The ³¹P and ¹⁹F chemical shifts and the computed FIAs of these fluorophosphonium cations correlate with the rankings of the relative Lewis acidities. Thus the NMR data can be employed as an indication of relative Lewis acidity within the series of fluorophosphonium cations, while the computed FIA provides a basis for comparison with other Lewis acid systems. The electrophilicity of fluorophosphonium cations is a topic of research which we continue to explore in our laboratory.
