This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
Syntheses and Reductions of C-Dimesitylboryl-1,2-dicarba-closo-dodecaboranes†‡

† In memory of Ken Wade, a brilliant chemist and mentor.

Abstract:
Two C-dimesitylboryl-1,2-dicarba-closo-dodecaboranes, 1-(BMes₂)-2-R-1,2-C₂B₁₀H₁₀ (1, R = H, 2, R = Ph), were synthesised by lithiation of 1,2-dicarba-closo-dodecaborane and 1-phenyl-1,2-dicarba-closo-dodecaborane, respectively, with n-butyllithium and subsequent reaction with fluorodimesitylboran. These novel compounds were structurally characterised by X-ray crystallography. Compounds 1 and 2 are hydrolysed on prolonged exposure to air to give mesitylene and boronic acids 1-(B(OH)₂)-2-R-1,2-C₂B₁₀H₁₀ (3, R = H, 4, R = Ph respectively). Addition of fluoride anions to 1 and 2 resulted in boryl-carborane bond cleavage to give dimesitylborinic acid HOBMes₂. UV absorption bands at 318-333 nm were observed for 1 and 2 corresponding to local π-π*-transitions within the dimesitylboryl groups while visible emissions at 541-664 nm with Stokes shifts of 11920-16170 cm⁻¹ were attributed to intramolecular charge transfer transitions between the mesityl and cluster groups. Compound 2 was shown by cyclic voltammetry to form a stable dianion on reduction. NMR spectra for the dianion [2]²⁻ were recorded from solutions generated by reductions of 2 with alkali metals and compared with NMR spectra from reductions of 1,2-diphenyl-ortho-carborane 5. On the basis of observed and computed ¹¹B NMR shifts, these nido-dianions contain bowl-shaped cluster geometries. The carborane is viewed as the electron-acceptor and the mesityl group is the electron-donor in C-dimesitylboryl-1,2-dicarba-closo-dodecaboranes.

.
Introduction

Tri-coordinate boron compounds have been intensely investigated in the past two decades in view of potential applications as functional materials.\(^1\) The most widely employed functional moiety containing a tri-coordinate boron atom is the dimesitylboryl group (BMes\(_2\); Mes = 2,4,6-\(\text{Me}_3\text{C}_6\text{H}_2\)) in which the unsaturated boron centre is kinetically stabilised by steric shielding of the mesityl groups. The empty \(p_z\)-orbital at the boron atom can interact with the \(\pi\)-system of attached organic skeletons which leads to a narrowing of the HOMO-LUMO-gap (HLG) by lowering the LUMO energy. Indeed, the \(\pi\)-acceptor strength of the BMes\(_2\) group is similar to those of cyano\(^2\) and nitro\(^3\) groups. These electronic characteristics have led to organic materials containing BMes\(_2\) units finding application as electron-transporting materials in opto-electronic devices.\(^4,5\) Compounds containing BMes\(_2\) can be strongly fluorescent and thus have been used in organic light emitting diodes (OLEDs).\(^5,6\) Moreover, the ability of the boron atom to form selectively covalent adducts with small anions has led to applications of these compounds as colorimetric and luminescent sensors for fluoride\(^7,9\) and cyanide.\(^10,11\)

Other boron-containing compounds that have gained considerable interest in the last seven years in the field of opto-electronic materials are derivatives of the dicarba-\(\text{closo}\)-dodecaborane isomers (1,2-, 1,7- and 1,12-C\(_2\)B\(_{10}\)H\(_{12}\) which are \(\text{ortho-}, \text{meta-}\) and \(\text{para}\)-carborane, respectively).\(^12,13\) Due to their delocalised \(\sigma\)-electron systems (‘3D aromaticity’), these clusters possess high thermal and chemical stabilities.\(^14\) The \(\text{ortho}\)-carborane is a unique electron-acceptor when connected to a donor at one or both cluster carbon atoms (at C1 and/or C2 in 1,2-C\(_2\)B\(_{10}\)H\(_{12}\)) due to the elasticity of the cluster C1-C2 bond.\(^15-17\) The \(\text{ortho}\)-carborane unit thus can play an active role as the acceptor in donor-acceptor molecules (dyads). Photoexcitation of such dyads induce a charge transfer from an organic scaffold to the carborane cluster which either led to luminescence quenching\(^18\) or to charge transfer (CT) emissions or both depending on the solvents used\(^19,21\) and whether the materials were investigated as solids.\(^22-28\) Compounds with both BMes\(_2\) and \(\text{ortho}\)-carboranyl groups are known\(^29,30\) with para-phenylene bridges linking both units. In these systems, the \(\text{ortho}\)-carboranyl group served as a strongly inductive electron-withdrawing group as the cluster increased the Lewis acidity of the triarylborane as found by fluoride ion titrations compared to the triarylborane without the cluster attached.\(^29\) Another compound containing both BMes\(_2\) and \(\text{ortho}\)-carboranyl group was reported with an ethenylene bridge linking both units.\(^31\)

Of the few \(\text{ortho}\)-carboranes with tri-coordinate boron substituents at their carbon atoms reported,\(^24,26,32-36\) only \(C\)-benzodiazaborolyl-\(\text{ortho}\)-carboranes have been investigated
regarding their photophysical, electrochemical and spectroelectrochemical properties.\textsuperscript{25} However, the benzodiazaboroly group generally acts as a π-donor and is therefore electronically quite distinct from the BMes\textsubscript{2} moiety. In order to better understand the photophysical and electrochemical properties of ortho-carboranes with boryl groups, studies with compounds containing a tri-coordinate boron π-acceptor would be appealing and allow one to determine more precisely the electronic interplay between the carborane and tri-coordinate boron electron-withdrawing units. Therefore we present herein, the syntheses and crystal structures of two ortho-carborane derivatives 1 and 2 with a BMes\textsubscript{2} group at one of the cage carbon atoms and their photophysical and electrochemical properties (Figure 1). The geometry of the reduced species of 2 was also determined by a combination of \textsuperscript{11}B NMR spectroscopy and GIAO-NMR DFT computations.

\textbf{Figure 1.} Syntheses of the novel C-dimesitylboryl-ortho-carboranes 1 and 2.

\textbf{Results and Discussion}

\textbf{Syntheses and characterisation of 1 and 2}

Compounds 1 and 2 were synthesised by reaction of fluorodimesitylborane with the corresponding C-lithiocarborane, generated \textit{in situ} by metallation of ortho-carborane and 1-phenyl-ortho-carborane, in boiling toluene (Figure 1). The elevated temperatures proved to be essential as no conversion was observed at ambient temperature. Purification was achieved by aqueous work-up and the target compounds were isolated in moderate yields by crystallisation from \textit{n}-hexane/dichloromethane mixtures. The elemental analytical result for 1 was significantly lower (0.8\% for carbon) than the calculated value. Similar discrepancies have been noted elsewhere for related compounds.\textsuperscript{33} It is possible that the formation of boron carbide during the combustion analysis may adversely affect the values obtained.
Signals in the $^{11}\text{B} \left(^1\text{H}\right)$ NMR spectra of 1 and 2 between 3.7 and -12.9 ppm confirm the presence of the ortho-carborane clusters. The $^{11}\text{B}$ peaks at 78.9 ppm (1) and 80.4 ppm (2) are assigned to the BMes$_2$ groups and are very broad compared to the peaks corresponding to the cluster. The $^{11}\text{B}$ chemical shifts of the Mes$_2$B groups in 1 and 2 are virtually identical to trimesitylborane (79.2 ppm) and phenyldimesitylborane (79.3 ppm). Thus, the ortho-carboranyl groups influence the chemical shift of the three-coordinate boron atom of the BMes$_2$ unit in the same manner as a phenyl or mesityl substituent.

**Hydrolyses of 1 and 2**

Since aqueous work-ups were used in the preparation of 1 and 2 these C-boryl-ortho-carboranes are considered to be water-stable - unlike many reported C-boryl-ortho-carboranes that could not be isolated pure due to facile hydrolysis. The $^1\text{H}$ and $^{11}\text{B}$ NMR spectra for 1 and 2 in deuterated chloroform solutions containing excess water also showed no changes. The sterics of the mesityl and the carboranyl groups appear to prevent facile hydrolysis of the boron atom in 1 and 2.

Solids of 1 and 2 do, however, hydrolyse on prolonged exposure to air (complete conversion after three weeks for 1 and eighteen months for 2) to give mesitylene and the new carboranylboronic acids, 3 and 4 (Figure 2). While these acids could not be obtained pure, they were identified by multinuclear NMR spectroscopies and mass spectrometries. The observed cleavage of the B-C(mesityl) bond in the process is not without precedent, it has been shown elsewhere that mesitylene is formed from the reaction of dimesitylborinic acid, Mes$_2$BOH, with trimethylaluminium. The initial steps in these air-induced hydrolyses of 1 and 2 probably involve cleavage of the B-C(mesityl) bonds by oxygen (as in the B-C(phenyl) bond cleavage reaction of triphenylboron by oxygen) followed by hydrolysis with traces of water present in air.
As many organic dimesitylboranes have been explored as fluoride sensors,\textsuperscript{7,29} the reactivity of 1 and 2 towards fluoride ions was of interest. Chloroform solutions of 1 and 2 were treated with an excess of tetra-\textit{n}-butylammonium fluoride hydrate (TBAFH) while acetonitrile solutions of 1 and 2 were added with potassium fluoride (KF) and 18-crown-6 to obtain the desired fluoride adducts [\textit{1·F}] and [\textit{2·F}], respectively, where the fluoride ion is bound to the boryl atom. Hydrolysis took place instead in all cases to give Mes\textsubscript{2}BOH, and the corresponding unsubstituted carborane, 1,2-C\textsubscript{2}B\textsubscript{10}H\textsubscript{12} or 1-Ph-1,2-C\textsubscript{2}B\textsubscript{10}H\textsubscript{11}, as detected by \textsuperscript{1}H, \textsuperscript{11}B, \textsuperscript{13}C and \textsuperscript{19}F NMR spectroscopies on the reaction mixtures (Figure 2). These reactions were complicated by fluoride-ion deboronation processes on the unsubstituted carboranes to give \textsuperscript{11}B and \textsuperscript{19}F NMR peaks corresponding to fluoroborates of the boron atom initially removed from the cluster.\textsuperscript{40}

It is possible that fluorodimesitylborane, Mes\textsubscript{2}BF, is initially formed in the reaction as Mes\textsubscript{2}BF is known to be easily hydrolysed to Mes\textsubscript{2}BOH.\textsuperscript{39,41} However, careful \textsuperscript{19}F NMR monitoring of the reaction mixtures from 1 and 2 with TBAFH in the first few minutes did not reveal any evidence of an intermediate such as the fluoride adducts [\textit{1·F}], [\textit{2·F}] or Mes\textsubscript{2}BF. The reactions of potassium hydroxide (KOH) and 18-crown-6 with 1 and 2 in acetonitrile gave Mes\textsubscript{2}BOH and the corresponding unsubstituted carborane. Deboronation products were also present in the latter reactions as the combination of KOH and 18-crown-6 is a strong deboronating agent.\textsuperscript{42}
X-ray crystallography
Single crystals of 1 and 2 were grown from *n*-hexane/dichloromethane mixtures and their molecular structures were determined by X-ray diffraction (Figures 3 and 4, Table 1). The BMes₂ groups adopt orientations with C2-C1-B1-C3 torsion angles at 36.0(2)° and 22.5(2)° and C2-C1-B1-C12 at -144.5(2)° and -157.8(2)° in 1 and 2 respectively (Table 1). Thus the empty pₓ-orbitals are approximately in plane with the C1-B3 bonds in the clusters and these C1-B3 bonds are shorter than the C1-B6 bonds by 0.02-0.03 Å in both compounds. However, all B-B and B-C bonds lengths in the clusters are within the usual range.²⁴

\textsuperscript{[a]} calculated values from optimised geometries of 1 and 2 at B3LYP/6-31G*. 
The C1-C2 distance of 1.677(3) Å in 1 agrees within 3 esd with C1-C2 bond lengths of 1.667(1)-1.673(1) Å found in other C-monoboryl-ortho-carboranes.\textsuperscript{24,33,36} By contrast, the C1-C2 bond of 1.761(2) Å in 2 is significantly longer than in its 1,3-diethyl-1,3,2-benzodiazaborol-2-yl analogue (1.701(2) - 1.730(2) Å),\textsuperscript{24} in 1,2-diphenyl-ortho-carborane (1.720(4)-1.733(4) Å)\textsuperscript{43} and 1,2-diboryl-ortho-carboranes (1.695(1)-1.725(2) Å).\textsuperscript{26,36} The longer C1-C2 bond in 2 is explained by the different steric interactions between the BMes\textsubscript{2} group at C1 and the phenyl ring at C2 in 2.

The BMes\textsubscript{2} groups are linked to the cage carbon atoms by B-C single bonds (C1-B1) with lengths of 1.635(3) Å in 1 and 1.629(2) Å in 2, which is at the upper edge of the range determined for other C-boryl-ortho-carboranes (1.607(4) - 1.649(12) Å).\textsuperscript{24-26,33,36} The B-C bond lengths between the mesityl rings and the boryl-boron atoms (B1-C3/C12 1.581(3) Å - 1.602(2) Å) are typical for dimesitylborylcarboranes. As a consequence of the three-dimensional shape of the cluster in both structures, the interplanar angle enclosed by the mesityl ring pointing towards the second cage carbon atom and the plane defined by the boryl-boron atoms and the three neighbouring carbon atoms (77.9(1)° (1), 78.6(1)° (2)) is larger than in most reported structures of BMes\textsubscript{2} compounds.\textsuperscript{44} A virtually perpendicular orientation of the phenyl substituent in 2 with respect to the C1-C2 axis (torsion angles = C1-C2-C21-C22 94.3(2)°, C1-C2-C21-C26 –91.5(2)°) corresponds to the situation in other disubstituted phenyl-ortho-carboranes and is preferred due to steric\textsuperscript{43,45}.

**Photophysics**

Photophysical data for 1 and 2 are listed in Table 2. The absorption maxima of both C-dimesitylboryl-ortho-carboranes (Figure S1) in solvents of different polarity do not display any significant solvatochromism. The lack of solvatochromism points to very similar dipole moments in the electronic ground state and the initial excited state indicating that local transitions within the dimesitylboryl unit give rise to the absorption bands observed. The presence of the phenyl ring at C2 in 2 appears to lower the HOMO-LUMO energy gap as the absorption maxima of 2 (330 nm - 333 nm) are bathochromically shifted by approximately 12 - 14 nm compared to 1 (318 - 319 nm) in all solvents used. The energy difference in the absorption maxima between 1 (329 nm) and 2 (332 nm) in the solid state is smaller.

Emission maxima of both compounds in cyclohexane are virtually identical at 541 nm for 1 and 544 nm for 2 with large Stokes shifts of 12300 cm\textsuperscript{-1} for 1 and 11920 cm\textsuperscript{-1} for 2. The luminescence spectra (Figure 5) reveal positive solvatochromism with emission maxima in
the more polar solvent dichloromethane in the red emission region at 664 nm for 1 and 643 nm for 2. By using the Lippert-Mataga method with an Onsager radius of 4.00 Å estimated from the molecular structures, the calculated transition dipole moments are 10.4 D (1) and 9.2 D (2) similar to transition dipole moments of C-benzodiazaborolyl-ortho-carboranes (6.9 - 10.9 D). The results show that the carborane cluster plays a part in the emission process acting as the electron acceptor of the charge transfer process after excitation. The solid-state emissions occur at longer wavelengths than in cyclohexane (Figure 6). This bathochromic shift is more pronounced for 1 (567 nm) than for 2 (550 nm) and is presumably caused by fluorophore-fluorophore interactions. The quantum yields (Φ) are very low in all solvents (< 1%) with higher values of 2% (1) and 7% (2) found in the solid state.

In addition to these low-energy emissions, compound 1 displays a weaker emission band at the violet edge of the visible spectrum in polar solvents. The high-energy emissions with smaller Stokes shifts of 4710 - 6600 cm⁻¹ probably originate from local transitions at the BMes₂ group. Similar dual emissions originating from both local and CT transitions have been reported for some ortho-carboranes with substituents at one or both cluster carbon atoms.

**Electrochemistry**

The electrochemical properties of both C-dimesitylboryl-ortho-carboranes 1 and 2 were investigated by cyclic voltammetry (CV, Figure 7). The peak potentials measured in acetonitrile and dichloromethane solutions, with platinum and glassy carbon working electrodes are listed in Table S1. The traces resemble reported CV data on reductions of carboranes elsewhere²⁰,²¹,²⁵-²⁷,⁴⁹-⁵⁴ and, by inference, reductions take place at the carborane clusters in 1 and 2. CV traces for reductions of the BMes₂ group would involve a simple one-electron reversible wave. In contrast, the one-electron reduction wave associated with PhBMes₂ occurs at -2.30 V (vs the ferrocenium/ferrocene couple at 0.0 V)² and hence the BMes₂ localised reduction in 1 and 2 likely falls outside the electrochemical window examined here.
Figure 7: Cyclic voltammograms of 1 and 2 with a glassy carbon working electrode in acetonitrile and internal ferrocenium/ferrocene couples at 0.0 V.

A CV trace for ortho-carborane or a C-monosubstituted-ortho-carborane usually shows a two-electron cathodic wave and an anodic wave that is not of the same current intensity as the cathodic wave.\textsuperscript{25,49,50} Often the peak-peak separation between the cathodic and anodic peaks of the wave can be several hundred millivolts due to the structural rearrangement of the dianion on the CV timescale. Decomposition and proton-coupled electron transfer (PCET) processes can also complicate the electrochemical response.\textsuperscript{49,55}

The CV of 1 in acetonitrile with a glassy carbon working electrode shows a two-electron cathodic wave at -1.85 V and two anodic waves at -1.40 V and -1.28 V with values referenced to the ferrocenium/ferrocene redox couple at 0 V (Figure 7). The cathodic wave value of -1.85 V for 1 means that 1 is more easily reduced than C-monophenyl-ortho-carborane at -2.25 V\textsuperscript{50} reflecting the substantial electron-withdrawing effect of the BMes\textsubscript{2} group. Similar CV traces are observed for 1 with a platinum working electrode and with DCM as solvent (Figure S2 and Table S1). The non-equivalent current intensities between the forward and reverse waves for 1 suggest that the dianion of [1]\textsuperscript{2-} is not stable and would be difficult to isolate.

A CV trace for ortho-carborane with aryl substituents at both cluster carbon atoms generally shows a reversible wave (or two) on reduction.\textsuperscript{20,25-27,49,51-54} In several cases, a stepwise reduction involving two separated one-electron reduction steps has been found, with the initial reduction process giving rise to a radical anion with an unusual 2n+3 skeletal electron (SE) count. One example is diphenyl-ortho-carborane 5 where the radical anion has been shown to be stable enough to be observed spectroscopically at ambient temperature in
solution (Figure 8).\textsuperscript{51} The first one-electron reduction process on the CV timescale is usually slow due to the rearrangement of the cluster and is often immediately followed by a second one-electron process giving an apparently two-electron cathodic wave. The latter wave is usually evident in DCM for these carboranes.\textsuperscript{26} However, on back oxidation two separate anodic waves (with the combined current intensities similar to the current intensity of the cathodic wave) are evident corresponding to two one-electron processes.\textsuperscript{25,26}

![Figure 8](image.png)

**Figure 8.** Two one-electron reductions for 1,2-diphenyl-ortho-carborane 5.

The CV of 2 in acetonitrile here shows two very closely spaced and barely resolved one-electron waves (Figure 7). These waves are separated by less than 80 mV based on gaussian analyses of square-wave potential traces (Figure S3). The two half-wave potentials are estimated to be -1.31 and -1.39 V which indicate that 2 is reduced more readily than diphenyl-ortho-carborane 3 at -1.57 and -1.72 V under the same CV conditions. Thus, compound 2 does form a radical anion with a 2n+3 skeletal electron count. However, the very low comproportionation constant (K_c) associated with the intermediate [2]\textsuperscript{-} means that spectroscopic observation is challenging, and the monoanion could not be isolated in any appreciable concentration in the comproportionated mixture obtained following one-electron reduction (Figure S4). The CV of 2 in DCM shows the expected CV pattern with a one two-electron cathodic wave and two one-electron anodic waves (Figure S2 and Table S1).

**Computations**

Calculated bond lengths and angles from geometries of 1 and 2 optimised at B3LYP/6-31G* are in good agreement with the experimental values (Table 1). The lengthening of the C1-B6 bonds compared to the C1-B3 bonds is attributed to steric repulsion between an ortho-methyl group of one of the mesityl rings and the B6-H unit. Computed energy barriers for the rotation around the C1-B1 bonds are 6.1 kcal·mol\textsuperscript{-1} in 1 and 18.6 kcal·mol\textsuperscript{-1} in 2. Comparison between
computed GIAO-NMR and experimental $^{11}$B NMR chemical shifts for 1-4 are in very good agreement (Table S2).

**Figure 9:** Frontier molecular orbitals of 1 (left) and 2 (right). The percentage values are the cluster contributions to the molecular orbitals.

The HOMO is a combination of $\pi$-orbitals at the mesityl groups ($\pi$(Mes)) and the LUMO consists mainly of the empty $p$-orbital of the boryl boron atom ($p$(B)) (Figure 9). Antibonding orbitals with significant cluster contributions have much higher energies (> -0.16 eV) and thus the influence of the clusters on the absorption process is merely inductive in both cases. According to TD-DFT calculations $\pi$(Mes)-$p$(B) transitions with oscillator strengths ($f$) of 0.0065 to 0.0698 can be assigned to the absorption bands of both compounds (Tables S3 and S4). Therefore, the electron density in the initially formed excited state is shifted within the BMes$_2$-unit only which is not expected to entail strong changes in the overall dipole moment. This is in agreement with the lack of solvatochromism in the absorption spectra. Weak transitions between the $\pi$-orbitals of the phenyl group of 2 and the $p$(B) orbital as well as $\pi$-$\pi^*$ transitions within the phenyl ring occur at considerably higher energy far in the UV region. The HOMO-LUMO gap energy of 2 is 0.10 eV smaller than that in 1 which agrees well with the observed bathochromic shift of the absorption maximum of 2 compared to 1.
In order to elucidate the origin of the visible CT emission of 1 and 2, their geometries were optimised at the first excited singlet state (S1). In both cases “open” cluster geometries were found with C1-C2 distances expanded to 2.384 Å (1) and 2.440 Å (2), respectively. The frontier orbitals of the S1 geometries are depicted in Figure 10. These orbitals were calculated at the ground state, S0 thus HOMO and LUMO correspond to the highest and second highest singly occupied orbitals in the S1 state. The HOMO is a π(Mes) orbital but the LUMO, in contrast, is an antibonding cluster orbital (cage*) with small contributions from the exopolyhedral boron atom (1: 15%, 2: 8%). Thus, the HOMO-LUMO transition corresponds to a charge transfer between the cluster and the mesityl groups from the excited state and the two compounds can be regarded as donor-acceptor systems. TD-DFT calculations predicted low-energy emissions with low oscillator strengths at 859 nm (1; f = 0.0016) and 783 nm (2; f = 0.0066) for these transitions and gave the same trend as experimentally observed with 1 emitting at longer wavelength than 2.

The geometries of the fluoride adducts [1·F−] and [2·F−] were optimised in order to examine why fluoride adducts were not observed experimentally. The fluoride ion affinities of 1 and 2 are 132.9 and 127.3 kcal·mol−1, respectively, which are higher than the fluoride ion affinities of many aryldimesitylboranes (Table 3). Although the strong carborane electron-withdrawing character increases the affinities for the fluoride ion in 1 and 2 with respect to the affinities of the aryldimesitylborane analogues, the optimised geometries [1·F−] and [2·F−]
contain unusually long B-C(carboranyl) bonds of 1.786 and 1.823 Å respectively. These bond lengths suggest that they would be easily cleaved either before the B-F bond is formed or by hydrolysis as observed experimentally.

Table 3. Calculated fluoride ion affinities in kcal·mol\(^{-1}\) for 1, 2 and related XBMes\(_2\) compounds in order of decreasing strengths.

Geometries of the dianions [2]\(^2\) and [5]\(^2\)

While closo-dicarbododecaboranes all adopt the pseudo-icosahedral geometry, several different geometries of nido-dicarbododecaborane dianions have been determined crystallographically (Figure 11).\(^{56}\) Dianions with almost planar C\(_2\)B\(_4\) open faces like [6]\(^2\) and [7]\(^2\) are observed in Group 1 metallacarboranes.\(^{57-60}\) Bowl-shaped geometries have been observed in carborane dianions like [8]\(^2\) and [9]\(^2\) with tethers at both cage carbons.\(^{59,61}\) The bowl geometry in [9]\(^2\) differs from that in [8]\(^2\) where [9]\(^2\) has a notably smaller open face.\(^{61}\) These bowl-shaped geometries are similar to geometries determined for neutral 12-vertex tetracarbododecaboranes by X-ray crystallography.\(^{62}\) The neutral compound 10 may also be regarded as a genuine 12-vertex dicarbododecaborane dianion [R\(_2\)C\(_2\)B\(_{10}\)H\(_{10}\)]\(^2\) with two positively charged phosphonium groups.\(^{63}\)
While there are several structural studies published on *nido*-dicarbadodecaborane dianions, the geometries of *nido*-dicarbadodecaborane dianions in solutions have not been determined. The successful method of comparing observed and computed $^{11}$B NMR data to determine carborane cluster geometries is applied here for dianion $[2]^2$. Before discussing the dianion $[2]^2$ made by chemical reductions on 2, the dianion $[5]^2$ generated from diphenyl-ortho-carborane 5 is described here to demonstrate the use of the combined experimental and calculated $^{11}$B NMR method in determining the geometry of its dianion. Dianion $[5]^2$ has been proposed to have a geometry with a C$_2$B$_4$ open face A or a geometry with a C$_2$B$_2$ open face B (Figure 12). Thus, the geometry of the dianion $[5]^2$ has not been established even though this dianion has been known for many decades.
Chemical reductions of 5 were carried out with alkali metals (Li, Na, K) in THF solutions. The reactions were monitored by $^{11}$B NMR spectroscopy until all the peaks corresponding to the starting carborane and the red colours of the solutions due to the radical monoanions disappeared. The $^{11}$B{$^1$H} spectra of the dianions [5]$^{2-}$ in clear yellow solutions show 2:2:4:2 patterns which are not significantly influenced by the different alkali metal cations (Figure 13). This pattern suggests a geometry of high symmetry or two mirror-image geometries that are fluctional in solution for [5]$^{2-}$ with the metal cations not strongly interacting in solution.

Figure 12. Geometries A-D of nido-dicarbododecaborane dianions with atom numbering.
Geometry optimisations on [5]$_2^-$ reveal that the bowl-shaped geometry C is more stable than A and B by 5.5 and 11.0 kcal mol$^{-1}$ respectively. More importantly, the computed GIAO $^{11}$B NMR chemical shifts of the bowl-shaped geometry fit well with observed shifts when fluctionality between the two mirror-image geometries of C takes place in solution (Table 4). The geometry D found in [9]$_2^-$ could not be located for [5]$_2^-$ where the initial geometry D rearranged to C on optimisation.
Table 4: Computed and observed $^{11}$B{$_1^1$H} NMR data of [2]$^{2-}$ and [5]$^{2-}$ in ppm and relative energies of the optimised geometries in kcalmol$^{-1}$.

[c] Calculated values are averaged assuming fluctuation between two mirror-image geometries; 10.0 (B10,12), -0.8 (B11), -6.0 (B8), -9.3 (B5,6), -18.8 (B3), -20.6 (B2,4), -25.6 (B1).

[d] Experimental data for sodium salt in d$_8$-THF.

Reduction of 2 with sodium metal in 1,2-dimethoxyethane (DME) yielded a dark red solid identified as [Na(DME)$_n$]$_2$[2] by $^1$H, $^{11}$B and $^{13}$C NMR spectroscopy. Purification of this extremely air-sensitive salt by crystallization was not successful. Salts of dicarbadodecaborane dianions are known to be extremely air- and moisture-sensitive.$^{57}$ The $^{11}$B{$_1^1$H} NMR spectrum recorded in CD$_3$CN revealed a 2:1:1:2:2:2 pattern for the cluster atoms and a very broad signal at 67.5 ppm corresponding to the boryl boron atom (Figure 14). The latter peak is considerably shifted to higher field by about 13 ppm compared to the neutral starting material.

Chemical reductions of the Mes$_2$B compound 2 in THF with alkali metals were carried out as for 5. After observation of the purple colours corresponding to the radical species and the disappearance of the peaks corresponding to the starting material, the clear solutions containing the dianions [2]$^{2-}$ were dark red. $^{11}$B NMR spectra of the dianions [2]$^{2-}$ show either a 2:1:1:2:2:2 (Li salt) or a 2:2:2:2:2 (Na, K) peak pattern (Figure 13) and are similar to peaks found for the diphenylcarborane dianions [5]$^{2-}$ when taking into account the lower symmetry in [2]$^{2-}$. 
The similarities in the $^{11}$B NMR peaks observed for $[2]^{2-}$ and $[5]^{2-}$ suggest that both have bowl-shaped geometries. Geometry optimisations on the $\text{BMes}_2$ species $[2]^{2-}$ reveal that the starting geometry $B$ was rearranged to the bowl-shaped geometry $D$. The most stable geometry for $[2]^{2-}$ is $C$ with $D$ only 0.8 kcal mol$^{-1}$ higher in energy. However, computed $^{11}$B NMR shifts from geometry $D$ fit better with observed $^{11}$B NMR shifts than geometry $C$ for $[2]^{2-}$ assuming fluctionalities between mirror-image geometries occur in solution (Figure 15).

It is concluded here that bowl-shaped geometries are present in solutions of 12-vertex $\text{nido}$-dicarbadodecaborane dianions with fluctional cluster geometries of $C$ and $D$ in dianions of $C,C'$-diphenyl-carborane $[5]^{2-}$ and $C$-dimesitylboryl-$C'$-phenyl-carborane $[2]^{2-}$ respectively. The calculated geometries for $[2]^{2-}$ and $[5]^{2-}$ are similar to the experimental cluster geometries of $[9]^{2-}$ and $[8]^{2-}$ respectively as shown from comparison of distances involving the cluster carbon atoms, C1 and C2, in Table 5. The combined experimental and calculated $^{11}$B NMR method is shown to be useful in determining $\text{nido}$-12-vertex geometries in solutions and will aid further progress on the intriguing range of $\text{nido}$-12-vertex geometries in the future.

Conclusions

Two C-dimesitylboryl-1,2-dicarba-closo-dodecaboranes were synthesised from fluorodimesitylboratione and the corresponding lithio-carboranes and structurally characterised by X-ray crystallography. Photophysical studies and TD-DFT calculations showed that the absorptions correspond to local transitions within the BMes$_2$ groups whereas visible emissions with Stokes shifts up to 16170 and 14800 cm$^{-1}$ in dichloromethane originate from intramolecular CT transitions between the mesityl rings and the cluster. Compound 2 with a phenyl substituent at the second cage carbon atom can be easily reduced to a stable dianion [2]$^{2-}$ by cyclic voltammetry and chemical reductions with alkali metals. Based on experimental and calculated $^{11}$B NMR data, a dynamic bowl-shaped nido-cage geometry is
determined for the dianion. These findings indicate that the ortho-carboranyl group is a stronger electron acceptor than the BMes$_2$ group and C-dimesitylboryl-1,2-dicarba-closo-dodecaboranes are dyads with the mesityl group as the donor and the carborane as the acceptor.

Experimental Section
General: The reactions were performed under an atmosphere of dry oxygen-free argon using Schlenk techniques. All solvents were dried by standard methods and freshly distilled prior to use. Fluorodimesitylboration$^{68}$ and 1-phenyl-1,2-dicarba-closo-dodecaborane$^{69}$ were prepared as described in the literature. 1,2-Dicarba-closo-dodecaborane was purchased commercially (KatChem). NMR spectra were recorded from solutions at room temperature on a Bruker AM Avance DRX500 ($^1$H, $^{11}$B, $^{13}$C), a Bruker Avance III 500 and a Bruker Avance 400 Spectrometer ($^1$H{$^{11}$B}, $^{19}$F) with SiMe$_4$ ($^1$H, $^{13}$C), BF$_3$·OEt$_2$ ($^{11}$B) and CFCl$_3$ ($^{19}$F) as external standards. $^1$H- and $^{13}$C{$^1$H} NMR spectra were calibrated on the solvent signal [CDCl$_3$: 7.24 ($^1$H), 77.16 ($^{13}$C); CD$_3$CN: 1.94 ($^1$H), 118.25, 1.32 ($^{13}$C); d$_8$-THF: 3.58, 1.73 ($^1$H), 67.57, 25.46 ($^{13}$C)]. The $^{13}$C NMR peaks were assigned with the aid of observed $^{13}$C DEPT spectra and computed $^{13}$C NMR shifts. Electron Ionisation (EI) and Atmospheric pressure Solids Analysis Probe (ASAP) mass spectra were recorded with a VG Autospec sector field (Micromass) and Xevo QTOF (Waters) mass spectrometers respectively.

1-Dimesitylboryl-1,2-dicarba-closo-dodecaborane (1):
A solution of n-butyllithium (1.6 M in n-hexane, 2.37 mL, 3.79 mmol) was added to 1,2-dicarba-closo-dodecaborane (0.52 g, 3.61 mmol) in toluene (35 mL) at 0 °C. After 16 h stirring at ambient temperature a solution of fluorodimesitylboration (0.96 g, 3.58 mmol) in toluene (6 mL) was added to the resulting suspension. The mixture was heated at reflux temperature for 5 h and washed with water (2 × 10 mL) and saturated sodium chloride
solution (10 mL) subsequently. The combined aqueous layers were extracted with toluene (10 mL) and the combined organic phases were dried over sodium sulfate and freed from volatiles in vacuo. The crude product was recrystallised from a mixture of n-hexane (30 mL) and dichloromethane (2 mL) to afford pure 1 as colourless crystals. Yield: 0.85 g (61 %). Found: C, 60.42; H, 8.51; N, 0.00 %; C_{20}H_{33}B_{11} requires C, 61.22; H, 8.48; N, 0.00 %; \textsuperscript{1}H-NMR (CDCl\textsubscript{3}): δ [ppm] = 1.4 - 3.2 (m, br, 10 H, BH), 2.24 (s, 6 H, \textit{para}-CH\textsubscript{3}), 2.40 (s, 12 H, \textit{ortho}-CH\textsubscript{3}), 3.85 (s, br, 1 H, B\textsubscript{10}H\textsubscript{10}C\textsubscript{2}H), 6.80 (s, 4 H, CH\textsubscript{Mes}); \textsuperscript{13}C{\textsuperscript{1}H}-NMR (CDCl\textsubscript{3}): δ [ppm] = 20.9 (s, \textit{para}-CH\textsubscript{3}), 25.9 (s, \textit{ortho}-CH\textsubscript{3}), 51.6 (s, CB\textsubscript{10}H\textsubscript{10}CH), 75.4 (s, CB\textsubscript{10}H\textsubscript{10}CB\textsubscript{Mes}2), 129.7 (s, CH\textsubscript{Mes}), 138.4 (s, C\textsubscript{ipso}), 139.4 (s, C\textsubscript{ortho}), 139.8 (s, C\textsubscript{para}); \textsuperscript{11}B{\textsuperscript{1}H}-NMR (CDCl\textsubscript{3}): δ [ppm] = –12.9 (s), –9.1 (s), –6.9 (s), –2.3 (s), 1.9 (s) (skeletal boron atoms), 78.9 (s, br, exopolyhedral boron atom) see Figures S5-S7 for NMR spectra of 1; MS (EI): m/z = 392.4 (M\textsuperscript{+}, 3 %), 272.3 (M\textsuperscript{+}–HMes, 51 %), 249.2 (BMes\textsubscript{2}\textsuperscript{+}, 46 %), 120.1 (Mes\textsuperscript{+}, 100 %).

1-Dimesitylboryl-2-phenyl-1,2-dicarba-closo-dodecaborane (2):
A solution of n-butyllithium (1.6 M in n-hexane, 3.10 mL, 4.96 mmol) was added to 1-phenyl-1,2-dicarba-closo-dodecaborane (0.97 g, 4.40 mL) in toluene (40 mL). After stirring for 16 h at ambient temperature a solution of fluorodimesitylboranee (1.30 g, 4.85 mmol) in toluene (12 mL) was added and the mixture was heated at reflux temperature for 5 h. Subsequently it was washed with water (2 × 15 mL) and saturated sodium chloride solution (15 mL). The combined organic phases were dried over sodium sulfate and the solvent was removed in vacuo. Impurities were sublimed from the residue at 80 °C in vacuo and the remaining solid was recrystallised from a mixture of n-hexane (80 mL) and dichloromethane (5 mL). The product 2 was obtained as colourless crystals. Yield: 0.97 g (51 %). Found: C, 66.38; H, 7.97; N, 0.00 %; C_{26}H_{37}B_{11} requires C, 66.66; H, 7.96; N, 0.00 %; \textsuperscript{1}H{\textsuperscript{11}B} NMR (CDCl\textsubscript{3}): δ [ppm] = 2.16 (s, 6 H, \textit{para}-UCH\textsubscript{3}), 2.26 (s, 14 H, BH + \textit{ortho}-UCH\textsubscript{3}), 2.33 (3H, BH), 2.41 (2H, BH), 2.70 (1H, BH), 3.47 (2H, BH), 6.56 (s, 4 H, CH\textsubscript{Mes}), 6.87 (dd, \textsuperscript{3}J\textsubscript{HH} = 7.4 Hz, \textsuperscript{3}J\textsubscript{HH} = 7.6 Hz, 2 H, H\textsubscript{meta}), 7.13 (t, \textsuperscript{3}J\textsubscript{HH} = 7.4 Hz, 1 H, H\textsubscript{para}), 7.18 (d, \textsuperscript{3}J\textsubscript{HH} = 7.6 Hz, 2 H, H\textsubscript{ortho}); \textsuperscript{13}C{\textsuperscript{1}H}-NMR (CDCl\textsubscript{3}): δ [ppm] = 20.8 (s, \textit{para}-CH\textsubscript{3}), 26.8 (s, \textit{ortho}-CH\textsubscript{3}), 86.5 (s, CB\textsubscript{10}H\textsubscript{10}CPh), 87.3 (s, CB\textsubscript{10}H\textsubscript{10}CB\textsubscript{Mes}2), 127.7 (s, C\textsubscript{meta, Ph}), 129.3 (s, C\textsubscript{para, Ph}), 129.4 (s, CH\textsubscript{Mes}), 130.3 (s, C\textsubscript{ortho, Ph}), 131.7 (s, C\textsubscript{ipso, Ph}), 138.8 (s, C\textsubscript{ipso, Mes}), 139.1 (s, C\textsubscript{para, Mes}), 139.4 (s, C\textsubscript{ortho, Mes}); \textsuperscript{11}B{\textsuperscript{1}H}-NMR (CDCl\textsubscript{3}): δ [ppm] = –9.9 (s), –8.0 (s), –2.8 (s), 3.7 (s) (skeletal boron atoms), 80.4 (s, br, exopolyhedral boron atom) see Figures S8-S10 for NMR spectra of 2; MS (EI): m/z = 468.4 (M\textsuperscript{+}, 4 %), 453.4 (M\textsuperscript{+}–Me, 2 %), 348.3 (M\textsuperscript{+}–HMes, 100 %), 323.2 (M\textsuperscript{+}–Me–Mes, 13 %), 249.2 (BMes\textsubscript{2}\textsuperscript{+}, 85 %).
Hydrolyses of 1 and 2

A drop of water (excess) was mixed with a solution of 1 or 2 in deuterated chloroform in an NMR tube and the mixture was analysed by NMR spectroscopy. No change in the spectra was observed after a week.

Hydrolysis by air exposure: Solids of 1 (0.2 g, 0.51 mmol) and 2 (0.3 g, 0.64 mmol) were left exposed to air in the laboratory and checked periodically by NMR spectroscopy. After three weeks, compound 1 was converted to mesitylene and carboranylborinic acid 3 as determined by multinuclear NMR spectroscopy. After eighteen months, mesitylene and borinic acid were identified as products of 2. Mesitylene: $^1$H NMR (CDCl$_3$): $\delta$ [ppm] = 6.81, 2.25; $^{13}$C ($^1$H) NMR (CDCl$_3$): $\delta$ [ppm] = 137.9, 127.0, 21.3. (1,2-Dicarba-closo-dodecaboranyl)-1-borinic acid (3): $^1$H ($^{11}$B) NMR (CDCl$_3$): $\delta$ [ppm] = 2.05 (2H, BH), 2.17 (2H, BH), 2.26 (2H, BH), 2.33 (4H, BH), 4.91 (2H, OH); $^{11}$B NMR (CDCl$_3$): $\delta$ [ppm] = –12.6 (s), –7.8 (s), –2.1 (s), –1.0 (s) (skeletal boron atoms), 26.5 (s, exopolyhedral boron atom) see Figure S11 for $^{11}$B NMR spectra of 3; MS (ASAP, M = C$_8$H$_{13}$B$_2$O$_2$) m/z = 188.0 (M$^+$, 21 %), 171.2 (M$^+$–OH, 100 %). (2-Phenyl-1,2-dicarba-closo-dodecaboranyl)-1-borinic acid (4): $^1$H NMR (CDCl$_3$): $\delta$ [ppm] = 2.32 (2H, BH), 2.42 (3H, BH), 2.48 (2H, BH), 2.61 (1H, BH), 2.92 (2H, BH), 4.46 (2H, OH), 7.34 (dd, $^3$J$_{HH}$ = 7.4 Hz, $^3$J$_{HH}$ = 7.6 Hz, 2 H, H$_{meta}$), 7.41 (t, $^3$J$_{HH}$ = 7.4 Hz, 1 H, H$_{para}$), 7.64 (d, $^3$J$_{HH}$ = 7.6 Hz, 2 H, H$_{ortho}$), $^{13}$C ($^1$H) NMR (CDCl$_3$): $\delta$ [ppm] = 20.8 (s, para-CH$_3$), 26.8 (s, ortho-CH$_3$), 86.5 (s, CB$_{10}$H$_{10}$CPh), 87.3 (s, CB$_{10}$H$_{10}$CBBmes$_2$), 127.7 (s, C$_{meta}$, Ph), 129.3 (s, C$_{para}$, Ph), 129.4 (s, CH$_{Mes}$), 130.3 (s, C$_{ortho}$, Ph), 131.7 (s, C$_{ipso}$, Ph), 138.8 (s, C$_{ipso}$, Mes), 139.1 (s, C$_{para}$, Mes), 139.4 (s, C$_{ortho}$, Mes); $^{11}$B ($^1$H) NMR (CDCl$_3$): $\delta$ [ppm] = –11.7 (s), –10.6 (s), –8.3 (s), –3.1 (s), 0.9 (s) (skeletal boron atoms), 26.5 (s, exopolyhedral boron atom) see Figure S12 for $^{11}$B NMR spectra of 4; MS (ASAP, M = C$_8$H$_{17}$B$_{11}$O$_2$) m/z = 263.2 (M$^{1+}$, 44 %), 247.2 (M$^+$–OH, 100 %).

Hydrolysis by fluoride ion: 1-Dimesitylboryl-1,2-dicarba-closo-dodecaborane (1) (0.009 g, 0.023 mmol) was dissolved in a solution of tetra-$n$-butylammonium fluoride trihydrate (0.014 g, 0.044 mmol) in deuterated chloroform (0.8 mL) and the mixture was subject to NMR spectroscopy. Likewise, 1-dimesitylboryl-2-phenyl-1,2-dicarba-closo-dodecaborane (2) (0.026 g, 0.055 mmol) was dissolved in a deuterated chloroform solution of tetra-$n$-
butylammonium fluoride trihydrate (0.018 g, 0.057 mmol). The products identified by multinuclear NMR spectroscopy were dimesitylboric acid, $\text{Mes}_{2}\text{BOH}$, and 1,2-dicarba-closo-dodecaborane$^{20}$ from 1 and $\text{Mes}_{2}\text{BOH}$ and 2-phenyl-1,2-dicarba-closo-dodecaborane$^{20}$ from 2. Deboronated products were also identified in the reaction mixtures from their NMR data (see Figure S13 for $^{19}$F NMR spectra).$^{40}$ Dimesitylboric acid: $^{1}$H-NMR (CDCl$_3$): $\delta$ [ppm] = 2.30 (12H), 2.32 (6H), 5.97 (1H, OH), 6.86 (4H); $^{13}$C {$^1$H}-NMR (CDCl$_3$): $\delta$ [ppm] = 21.3, 22.6, 128.5, 137.0, 139.5, 141.2; $^{11}$B-NMR (CDCl$_3$): $\delta$ [ppm] = 50.1.

**Reductions of 2 and 5**

Method 1: A piece of excess sodium metal was added to a solution of 1-dimesitylboryl-2-phenyl-1,2-dicarba-closo-dodecaborane 2 (0.07 g, 0.14 mmol) in 1,2-dimethoxyethane (0.5 mL). A dark red colour occurred immediately on the surface of the metal. The mixture was sonicated for 1 h and filtered subsequently. The filtrate was freed from volatiles in vacuo and the dark red remainder was taken up in d$_3$-acetonitrile and analysed by NMR spectroscopy. $^1$H NMR (CD$_3$CN): $\delta$ [ppm] = −0.4 - 3.0 (m, br, 10 H, BH), 2.15 (s, 6 H, $para$-CH$_3$), 2.32 (s, 12 H, $ortho$-CH$_3$), 6.52 (s, br, 4 H, CH$_{\text{Mes}}$), 6.76 (s, br, 1 H, $para$-H$_{\text{H}}$), 6.92 (s, br, 2 H, H$_{\text{Ph}}$), 7.43 (s, br, 2 H, H$_{\text{Ph}}$); $^{13}$C {$^1$H} NMR (CD$_3$CN): $\delta$ [ppm] = 20.8 (s, $para$-CH$_3$), 25.1 (s, $ortho$-CH$_3$), 70.5 (s, CB$_{10}$H$_{10}$CPh), 106.7 (s, CB$_{10}$H$_{10}$CB$_{\text{Mes}}$), 122.0 (s, CH$_{\text{Ph}}$ $para$), 127.6 (br s, CH$_{\text{Mes}}$, CH$_{\text{Ph}}$ $meta$), 128.7 (s, CH$_{\text{Ph}}$ $ortho$), 133.6 (s, s, C$_{\text{Mes}}$$para$), 140.9 (s, C$_{\text{Mes}}$$ortho$), 149.4 (s, C$_{\text{Mes}}$$ipso$), 154.2 (s, C$_{\text{Ph}}$ $ipso$); $^{11}$B {$^1$H} NMR (CD$_3$CN): $\delta$ [ppm] = −27.2 (s), −17.8 (s), −14.0 (s), −10.1 (s), −9.2 (s), 0.1 (s) (skeletal boron atoms), 67.5 (s, br, exopolyhedral boron atom); see Figure 14; UV-Vis for [2]$^{2-}$ in CH$_3$CN, [nm (ε)] = 344 (4600), 405 (1700), 430 (1400), 515 (1300) (Figure S4).

Method 2: Finely-cut alkali metal pieces were added to a solution of 2 (0.07 g, 0.14 mmol) in tetrahydrofuran (0.5 mL). A purple colour occurred immediately at the metal surface followed by a clear dark red solution after 2 h. The reaction mixture was then analysed by $^{11}$B NMR spectroscopy and in many experiments the desired di-anion was present as the carborane compound (Table S5). $^1$H and $^{13}$C NMR spectra were also obtained for Na$_2$[2] when deuterated THF was used in place of THF. Na$_2$[2]. $^1$H {$^{11}$B} NMR (d$_8$-THF): $\delta$ [ppm] = 0.26 (s, 2 H, BH), 1.16 (s, 2 H, BH), 1.59 (s, 2 H, BH), 2.09 (s, 6 H, $para$-CH$_3$), 2.19 (s, 1 H, BH), 2.35 (s, 12 H, $ortho$-CH$_3$), 6.46 (s, 4 H, CH$_{\text{Mes}}$), 6.68 (t, 7.5 Hz, 1 H, $para$-H$_{\text{H}}$), 6.82 (apparent triplet, ~8 Hz, 2 H, H$_{\text{Ph}}$ $meta$), 7.37 (d, 8 Hz, 2 H, H$_{\text{Ph}}$ $ortho$); $^{13}$C {$^1$H} NMR (d$_8$-THF): 21.3 (s, $para$-CH$_3$), 122.3 (s, CH$_{\text{Ph}}$ $para$), 126.7 (s, CH$_{\text{Ph}}$ $meta$), 127.7 (s, CH$_{\text{Mes}}$), 128.9 (s, CH$_{\text{Ph}}$ $ortho$), 133.1 (s, C$_{\text{Mes}}$$para$), 140.8 (s, C$_{\text{Mes}}$ $ortho$), 148.7 (s, C$_{\text{Mes}}$ $ipso$), 153.5 (s, C$_{\text{Ph}}$ $ipso$);
the peak corresponding to ortho-CH₃ groups is hidden within the d₈-THF peak and the peaks for the cage carbons were not detected above the noise levels, see Figures S14 and S15 for \(^1\)H\{\(^{11}\)B\} and \(^{13}\)C NMR spectra. Exposing the dark red solution containing Na₂[2] slowly to air gave a light yellow solution identified by NMR spectroscopy to contain a mixture of the starting material 2 and 1-phenyl-ortho-carborane in a 9:1 ratio. Method 2 was also used in the reductions of 5 with alkali metals (Li, Na, K) but with deuterated THF in all cases and NMR data of M₂[5] (M = Li, Na, K) are listed in Table S6.

**Photophysical measurements**

For all solution state measurements, samples were contained in quartz cuvettes of 10 × 10 mm (Hellma type 111-QS, suprasil, optical precision). Cyclohexane was used as received from commercial sources (p. a. quality), the other solvents were dried by standard methods prior to use. Concentrations varied from 20 to 100 µM in order to get analysable emission spectra due to the low quantum yields. Effects of the concentration on the shape of the observed emission spectra were excluded in this concentration range. Solid samples were prepared by vacuum sublimation on quartz plates (35 × 10 × 1 mm) using standard Schlenk equipment and conditions. Each plate was laid in a 100 mL round bottom flask and a crystal of the sample substance placed below it was sublimed. Absorption was measured with a UV/VIS double-beam spectrometer (Shimadzu UV-2550), using the solvent as a reference.

The output of a continuous Xe-lamp (75 W, LOT Oriel) was wavelength-separated by a first monochromator (Spectra Pro ARC-175, 1800 l/mm grating, Blaze 250 nm) and then used to irradiate a sample. The fluorescence was collected by mirror optics at right angles and imaged on the entrance slit of a second spectrometer while compensating astigmatism at the same time. The signal was detected by a back-thinned CCD camera (RoperScientific, 1024 \× 256 pixels) in the exit plane of the spectrometer. The resulting images were spatially and spectrally resolved. As the next step, one averaged fluorescence spectrum was calculated from the raw images and stored in the computer. This process was repeated for different excitation wavelengths. The result is a two-dimensional fluorescence pattern with the y-axis corresponding to the excitation, and the x-axis to the emission wavelength. The wavelength range is λₘᵢₓ = 230-430 nm (in 1 nm increments) for the UV light and λᵢₘᵢₓ = 305-894 nm for the detector. The time to acquire a complete EES is typically less than 15 min. Post-processing of the EES includes subtraction of the dark current background, conversion of pixel to wavelength scales, and multiplication with a reference file to take the varying lamp intensity as well as grating and detection efficiency into account. Stokes shifts were calculated.
from excitation and emission maxima, which were extracted from spectra that were converted from wavelength to wavenumbers beforehand. The quantum yields in solution were determined against POPOP ($\rho$-bis-5-phenyl-oxazolyl(2)-benzene) ($\Phi_F = 0.93$) as the standard.

The solid-state fluorescence was measured by addition of an integrating sphere (Labsphere, coated with Spectralon, Ø 12.5 cm) to the existing experimental setup. At the exit slit of the first monochromator the exciting light was transferred into a quartz fibre (LOT Oriel, LLB592). It passed a condensor lens and illuminated a 1 cm$^2$ area on the sample in the centre of the sphere. The emission and exciting light was imaged by a second quartz fibre on the entrance slit of the detection monochromator. Post-processing of the spectra was done as described above. The measurement and calculation of quantum yields was performed according to the method described by Mello.\textsuperscript{71}

**Electrochemistry**

Cyclic voltammetric measurements were carried out using an EcoChemie Autolab PG-STAT 30 potentiostat at 298 K with a platinum or glassy carbon working electrode and platinum wires as counter and reference electrodes in a nitrogen-containing glove box with 0.1 M $\text{nBu}_4\text{NPF}_6$ in dichloromethane or acetonitrile. Scan rates of 100 mV s$^{-1}$ and analyte concentrations of $10^{-3}$ M were used. The ferrocene/ferrocenium $\text{FcH}/\text{FcH}^+$ couple served as internal reference at 0.0 V for potential measurements and peak-peak separations of this couple were generally in the region of 90-110 mV.

The spectroelectrochemical (SEC) experiment on 2 was performed at room temperature in an airtight optically transparent thin-layer electrochemical (OTTLE) cell\textsuperscript{72} equipped with Pt minigrid working and counter electrodes (32 wires cm$^{-1}$), Ag wire pseudo-reference electrode and CaF$_2$ windows for a 200 µm path-length solvent compartment. Acetonitrile containing 0.1 M $\text{[Bu}_4\text{N}\text{][PF}_6]$ electrolyte was used in the cell which was fitted into the sample compartment of a Cary 5000 (UV-Vis-NIR) spectrophotometer. Bulk electrolysis was carried out using an Autolab PG-STAT 30 potentiostat.

**Crystallographic studies**

Single crystals were coated with a layer of hydrocarbon oil and attached to a glass fiber. Crystallographic data were collected with a Bruker AXS X8 Prospector Ultra APEX II diffractometer with Cu-K$\alpha$ radiation (graphite monochromator, $\lambda = 1.54178$ Å) at 100 K. Crystallographic programs used for structure solution and refinement were from SHELX-97.\textsuperscript{73}
The structures were solved by direct methods and were refined by using full-matrix least squares on $F^2$ of all unique reflections with anisotropic thermal parameters for all non-hydrogen atoms. The hydrogen atoms bonded to the carborane units were refined isotropically, all other hydrogen atoms were refined using a riding model with $U(H) = 1.5 \ U_{eq}$ for CH$_3$ groups and $U(H) = 1.2 \ U_{eq}$ for all others. Crystallographic data for the compounds are listed in Table S7. CCDC-1048027 (1) and CCDC-1048028 (2) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge from the Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

**Computational details**

All computations were carried out with the Gaussian 09 package. The model geometries were fully optimised with the B3LYP functional with no symmetry constraints using the 6-31G* basis set for all atoms. Frequency calculations on all optimised geometries revealed no imaginary frequencies. Computed absorption data were obtained from TD-DFT calculations on $S_0$ geometries whereas computed emission data were from the $S_1$ geometries. The MO diagrams and MO compositions were generated with the Molekel and GaussSum packages, respectively. Calculated $^{11}$B and $^{13}$C NMR chemical shifts obtained at the GIAO-B3LYP/6-31G*/B3LYP/6-31G* level on the optimised geometries were referenced to BF$_3$·OEt$_2$ for $^{11}$B: $\delta \ (^{11}\text{B}) = 111.7 - \sigma \ (^{11}\text{B})$ and referenced to TMS for $^{13}$C: $\delta \ (^{13}\text{C}) = 189.4 - \sigma \ (^{13}\text{C})$. Computed NMR values reported here were averaged where possible.

**References**

44. A search in the CCDC database in May 2012 revealed that 95% of the B-C\(_{\text{Mes}}\) bond lengths in 37 structures of \(p\)-substituted dimesitylborylbenzene derivatives are in the range of 1.55 Å - 1.61 Å. The interplanar angles between the mesityl rings and the planes defined by the boryl-boron atom and the three neighboring carbon atoms were found between 42.9° and 67.5° in these structures.

Graphical Abstract

Syntheses and Reductions of C-Dimesitylboryl-1,2-dicarba-closo-dodecaboranes

An investigation of C-dimesitylboryl-ortho-carboranes, 1-(BMes₂)-2-R-1,2-C₂B₆H₁₀ (1 and 2), reveals that the carborane is the electron-acceptor and the mesityl group is the electron-donor in these dyads.
