Accepted Manuscript

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about *Accepted Manuscripts* in the **Information for Authors**.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard <u>Terms & Conditions</u> and the <u>Ethical guidelines</u> still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

The addition of bromine and iodine on palladacyclopentadienyl complexes bearing bidentate heteroditopic P—N spectator ligands derived from differently substituted quinolinic frames. The unexpected evolution of the reaction.

Luciano Canovese, Fabiano Visentin, Thomas Scattolin, Claudio Santo and Valerio Bertolasi

The palladacyclopentadienyl complexes with substituted phosphoquinolines react with halogens giving σ -butadienyl or a zwitterionic derivative depending of the ligand structure.

The addition of bromine and iodine on palladacyclopentadienyl complexes bearing bidentate heteroditopic P—N spectator ligands derived from differently substituted quinolinic frames. The unexpected evolution of the reaction.

Abstract

We have synthesized two palladacyclopentadienyl derivatives bearing the bidentate ligands heteroditopic 8–(diphenyl phosphino)quinoline or 8–(diphenyl phosphino)–2–methylquinoline . We have reacted the palladacyclopentadienyl complexes with Br_2 and I_2 to gain clues on the formation mechanism of the corresponding σ –butadienyl derivatives. We were able to obtain the pure σ –butadienyl derivative only in the case of Br_2 reacting with the palladacyclopentadienyl complex bearing the unsubstituted quinoline. Instead, an equilibrium mixture of the σ –butadienyl and a novel zwitterionic species was obtained when the same complex reacts with I_2 . Furthermore, we have obtained exclusively an unprecedented zwitterionic complex when I_2 reacts with the palladacyclopentadienyl complex bearing the substituted quinoline and a different ratio of an equilibrium mixture of σ –butadienyl and the zwitterionic species when the latter derivative reacts with Br_2 . The solid state structures of one σ –butadienyl complex and of the two novel zwitterionic derivatives were determined and an interpretation of the observed reactivity based on kinetic data and a computational study has been suggested.

Introduction

A number of catalyzed reactions are based on the stability and chemical versatility of palladium complexes toward oxidative addition and reductive elimination. In particular, the interconversion between Pd(0) and Pd(II) derivatives ¹ has been widely studied since it often represents the keystone for several cross coupling processes. On the contrary, the red–ox reactions involving the Pd(II)–Pd(IV)–Pd(II) conversions are comparatively less investigated and are often related to addition of halogens or organic halides in catalytic ² or stoichiometric ³ processes yielding conjugated dienes as their final products. The conjugated dienes are important compounds contained in many natural and bioactive products. Therefore, their synthesis is of remarkable importance as testified by the development of catalytic protocols based on cobalt, ⁴ ruthenium, ⁵ nickel ⁶ and palladium. ^{6b, 7} Particular emphasis has been placed on the reactivity of palladacyclopentadienyl derivatives bearing different spectator ligands. ^{2, 3, 8} We have recently carried out a detailed study on the oxidative addition of I₂ to palladacyclopentadienyl complexes bearing monodentate isocyanides as spectator ligands. We were able to measure the rates of intramolecular conversion of the intermediate *trans*–diiodo palladium(IV) into the

cis-diisocyanide-tetramethyl pallada-1-iodobuta-1,3-diene-1,2,3,4-tetracarboxylate, its subsequent isomerisation to the *trans*-isomer, and support the experimental results with a computational study. ⁹

We also think that the conversion of the metallacyclopentadienyl complexes into the σ -butadienyl derivatives deserves further study since the stereospecific formation of the final butadienyl fragment is mainly governed by the transition state and the intermediate structures involved in this first step. We have therefore synthesized two palladacyclopentadienyl complexes bearing the bidentate heteroditopic ligands 8–(diphenyl phosphino)quinoline (DPPQ) or 8–(diphenyl phosphino)–2–methyl quinoline (DPPQ–Me) which, while avoiding complications arising from *cis–trans* isomerization of the spectator ligands, impart to the palladium derivatives properties that could be exploited in insertion reactions, 10 isomerization of a coordinated olefin 11 and nucleophilic attack on the allyl fragment. 12 We have finally studied from the experimental and theoretical point of view the oxidative addition of the cited complexes using bromine and iodine.

The ligands, the palladacyclopentadienyl and the identified σ -butadienyl complexes are reported in the following Scheme 1.

Scheme 1 Ligands, starting complexes and identified σ -butadienyl derivatives

Results and Discussion

Synthesis of the Cyclometallated Complexes 1a and 1b

The addition in acetone of the ligands DPPQ ¹³ or DPPQ-Me ¹⁴ under an inert atmosphere (Ar) to the polymer [PdC₄(COOMe)₄]_n which was synthesized using published procedures, ¹⁵ yields the complexes **1a** or **1b** which were easily isolated with good yield. These compounds are characterized by the downfield shift of the phosphorus (ca. 40 ppm) and of the quinoline <u>H</u>² (complex **1a**) or C<u>H</u>₃ (complex **1b**) protons, with respect to the free ligands in the ³¹P NMR and ¹H NMR spectra. There are also distinct signals related to four different COOCH₃ groups in the ¹H and ¹³C NMR spectra (see **Supplementary Information**: Fig. 1SI). Notably, at variance with the pyridylthioether palladacyclopentadienyl species, ^{8g} complexes **1a** and **1b** display no tendency for rotation of the spectator ligands (i.e. exchange of coordination sites between the different donor atoms).

Reactivity of Complex 1a with Br₂

As can be seen in Scheme 1, complex **1a** reacts with Br₂ to give the expected σ -butadienyl derivative **2a**. The formation of **2a** is apparent as can be deduced from the 1 H, 13 C and 31 P NMR spectra in CDCl₃ of the reaction product after precipitation from the concentrated reaction mixture with diethyl ether (see **Supplementary Information**: Fig. 2SI). As a matter of fact, the persistence of four different COOCH₃ groups with marked downfield shifts of the quinoline H² ($\delta \approx 10.5$ ppm clearly indicating its *cis* position to bromide 12) compared to those of the precursor, and the phosphorus peak ($\delta = 34.3$ ppm) show the course of the reaction.

Due to its stability in solution and in the solid state it was possible to confirm definitively the structure of **2a** as inferred from NMR, by X-ray diffraction. In Fig. 1 we report the ORTEP ¹⁶ representation of the solid state structure of complex **2a** which will be discussed later.

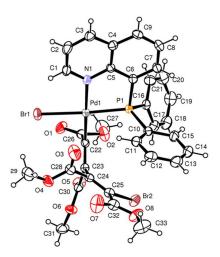

Fig. 1 ORTEP view of complex 2a showing the thermal ellipsoids at 30% probability level.

Reactivity of Complex 1b with Br₂

The reaction of complex **1b** with bromine under similar experimental conditions gives immediately the complex **2b** which can be quantitatively separated from the reaction mixture when precipitation with diethyl ether is induced soon after the addition of the Br₂ and at low temperature (273 K). The NMR spectra of the complex **2b** are very similar to those of **2a**. In particular the ³¹P singlet of the former is almost isochronous to that of the latter ($\delta = 34.2$ ppm) (see **Supplementary Information**: Fig. 3SI).

Complex **2b**, however, is not stable in solution and in about 30 h undergoes a remarkable change which is evident when the NMR spectra of the starting and the final derivative are compared. In fact, the phosphorus peak shifts upfield by about 20 ppm and the signals ascribable to the four OCH₃ groups resonate in different positions in the ¹H NMR spectrum (see **Supplementary Information**: Fig. 4SI).

However, the key contribution to understanding the nature of the new species (**4b**) was the determination of its solid state structure which is reported in Fig. 2 (again, the discussion of the structure will be dealt with in another section).

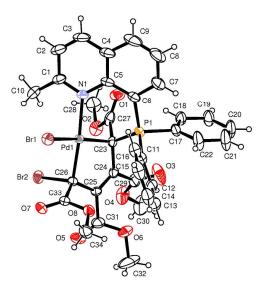

Fig. 2 ORTEP view of complex 4b showing the thermal ellipsoids at 30% probability level.

According to the structure of **4b**, the 13 C NMR spectrum shows a doublet at ca. 42 ppm ($J_{CP} \approx 60$ Hz) and a singlet at ca. 31 ppm ascribable to the alkyl carbons bound to the palladium centre. The reaction and the suggested mechanism yielding this unprecedented complex **4b** is shown in Eqn (1):

$$R_{\text{poly}}$$
 R_{poly}
 R_{\text

The formation of the zwitterionic complex **4b** might be explained as the result of an intramolecular nucleophilic attack of the phosphorus originally coordinated to the metal on the sp² carbon of the butadienyl fragment. The overall process is a slow equilibrium reaction and the amount of complex **2b** that remained unreacted was evaluated to be 15% of its initial concentration ($K_E \approx 5.4$). ¹⁷ Thus, it was possible to calculate k_f and k_r independently by non linear regression of the concentration vs. time data implemented in the SCIENTIST[®] computing environment.

The k_f and k_r values were estimated to be $(4.93 \pm 0.01)x10^{-5}$ and $(8.93 \pm 0.02)x10^{-6}$ s⁻¹, respectively. ¹⁸ The equilibrium constant was calculated as $K = k_f/k_r = 5.52 \pm 0.02$ which is in good agreement with the value determined from the experimentally detected final concentrations of the species **2b** and **4b** ($K \approx 5.4$) (See also footnote SI 1 in **Supplementary Information**).

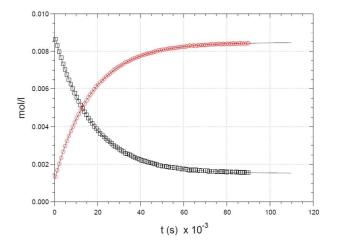

Fig. 3 ¹H NMR concentration profiles of **2b** (squares) and **4b** (circles) *vs.* time (s) for the reaction: **2b** = **4b** in CDCl₃ at 298 K.

It is noteworthy that it was not possible to obtain the derivative **4a** from the complex **1a**. As a matter of fact, when the reaction of complex **1a** with Br₂ was carried out for prolonged time at high temperature in CDCl₃ (323 K) a massive decomposition occurred.

Reactivity of Complexes 1b with I₂.

The addition at RT of an equimolecular amount of I_2 to a solution of **1b** in CH_2Cl_2 gives readily and quantitatively the complex **5b** as the only reaction product (Eqn. (2)).

Ph₂P N
$$I_2$$
 Pd I_2 Ph₂P I_2 Pd I_3 I_4 I_5 I_5

Complex **5b** displays NMR spectra very similar to those of complex **4b** previously described; in particular, the single signal in the 31 P NMR spectrum resonates at 8.9 ppm, whereas the 13 C NMR spectrum shows the characteristic peaks of the Pd–C–PPh₂ (doublet at ca. 44 ppm, J_{CP} = 61.8 Hz) and Pd–C–I (singlet at 32.9 ppm) (see **Supplementary Information**: Fig. 5SI). Again the structure of the derivative **5b** was definitively resolved by X–Ray diffractometry as reported in the **Crystal Structure Determination** section (Fig. 4) .

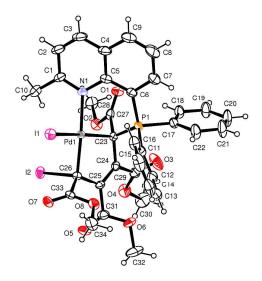

Fig. 4 ORTEP view of complex 5b showing the thermal ellipsoids at 30% probability level.

However, when the reaction is carried out at low temperature (253 K) it is possible to observe the formation of complex **3b** which was identified on the basis of the similarity of its ¹H and ³¹P NMR spectra with those of the parent complex **3a** (*vide infra*). As expected, complex **3b** readily reverts to complex **5b** at RT (See **Supplementary Information**: Fig. 6SI).

Complex 1a when reacting with I_2 predictably takes the middle course and an equilibrium mixture of the σ -butadienyl 3a and zwitterionic 5a complexes is detectable in solution. In Fig. 5 the 1 H and 31 P NMR spectra of the equilibrium mixture of complexes 3a and 5a taken soon after the addition of I_2 to 1a are reported. Remarkably, the immediately established concentration ratio between isomers remains constant over time.

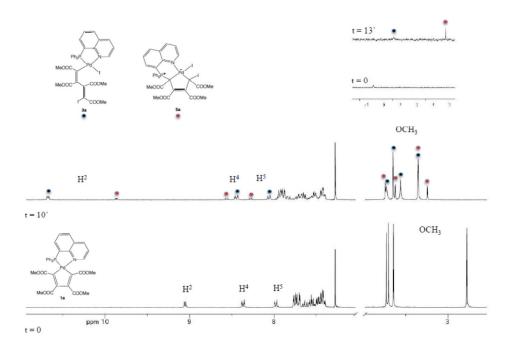

Fig. 5 ¹H and ³¹P NMR spectra of the starting complex **1a** (bottom) and of the equilibrium mixture of complexes **3a** and **5a** (top) in CDCl₃ at 298 K.

A summary of the oxidative additions of Br₂ and I₂ on complexes **1a** and **1b** is reported in the following Scheme 2 in which the complexes within dotted squares (**4a**, **3b**) have not been isolated.

Scheme 2 General overview of the reactivity of complexes 1a and 1b towards the addition of Br₂ and I₂

Reactivity of complex 2b with Γ .

In order to gain some more information about the driving force promoting the widening of the coordinative ring, we have reacted complex 2b ($[2b]_0 \approx 1 \times 10^{-2}$ mol dm⁻³) with two equivalents of $(n\text{-Bu})_4\text{NI}$, in CD₂Cl₂ at 298 K. The ^1H and ^{31}P NMR spectra of the reaction mixture in CD₂Cl₂ show that an equilibrium reaction between the starting complex 2b and a new species $2b^*$ is immediately established. Complex $2b^*$ was formed as a consequence of the substitution of the Br coordinated to palladium with iodide. The equilibrium mixture is slowly converted into a new equilibrium mixture of the zwitterions 4b and $4b^*$, as summarized in Scheme 3. The presence of complex 4b was proved by comparison with the ^1H and ^{31}P NMR spectra of an authentic sample of 4b. The structure of $4b^*$ was instead assessed by the comparison with the ^1H and ^{31}P NMR spectra of the complex obtained by reacting complex 4b with an excess (2:1) of $(n\text{-Bu})_4\text{NI}$ (6c). In the latter case, only the bromide coordinated to palladium should be substituted according with the well

established theory of the nucleophilic substitution on square planar complexes ¹⁹. (See Scheme 3 and **Supplementary Information**: Fig. 7a-c SI)

Scheme 3 Schematic representation of the equilibrium reactions triggered by the addition of (*n*-Bu)₄NI to complex **2b** in CD₂Cl₂ at RT.

As already stated, complex **3b** is not stable and immediately gives the zwitterion **5b** at RT. On the contrary, since the parent complex **2b*** reacts slowly to yield the zwitterion **4b*** it is reasonable to surmise that the halide bound to sp² carbon is also determinant in modulating the reaction rate. In summary, the rate of the reaction yielding the zwitterionic complexes seems to be due to an interplay of three different factors, *i.e.* the distortion of the coordinating ring, ^{10a, 10b, 11, 20} the *trans* influence of the halide *trans* to quinoline phosphorus, and the charge density on the butadienyl sp² carbon (which is clearly influenced by the electronegativity of the bound halide). Therefore, the best combination favoring the widening of the coordinated ring is the presence of the methyl substituted quinoline (and the consequent induced distortion of the original coordinative ring), the iodide *trans* to quinoline phosphorus, and the iodide bound to the butadienyl sp² carbon. Conversely, the other end is represented by the unsubstituted quinoline and the bromides bound to the palladium and to butadienyl sp² carbon.

Computational Study

Such an experimental observations were not in contrast with a detailed computational study carried out by the Gaussian 09 program. ²¹ To save computer time the carboxymethyl group COOMe was replaced by the less disordered CN moiety. (In the following discussion the CN derivatives will maintain the same labels of the original complexes marked with an apex).

Taking into account the limitations due to the errors implicit in this sort of calculation ($\Delta\Delta G^{\circ} \approx \pm 2$ kcal mol⁻¹) and the replacement of COOMe with CN groups, it was calculated that:

- i) Complex **4b'** is more stable than complex **2b'** by 2.3 kcal mol^{-1} .
- *ii)* Complex **5b'** is more stable than complex **3b'** by $5.0 \text{ kcal mol}^{-1}$.
- *iii*) Complex **4a'** is less stable than complex **2a'** by $0.9 \text{ kcal mol}^{-1}$.
- *iv)* Complex **5a'** is less stable than complex **3a'** but the difference is reduced if compared with the former ($\Delta G^{\circ} = 0.5 \text{ kcal mol}^{-1}$).

(See Supplementary Information Figs. 8SI for a schematic comparison)

The assessed energy values agree with the experimental results and in particular they account for the observed equilibrium distribution between complexes 2b' and 4b' ($\Delta G^{\circ} = 2.3 \text{ kcal mol}^{-1}$) and complexes 3a' and 5a' ($\Delta G^{\circ} = 0.5 \text{ kcal mol}^{-1}$). The higher difference in energy between complex 3b' and 5b' ($\Delta G^{\circ} = 5.0 \text{ kcal mol}^{-1}$) is consistent with the fact that complex 5b was the only isolated species, but it does not fully explain the behavior of complexes 2a' and 4a'. Although the higher energy of complex 4a' is clearly apparent, the calculated $\Delta\Delta G^{\circ}$ ($0.9 \text{ kcal mol}^{-1}$) would be indicative of an equilibrium distribution.

However, since no equilibrium is experimentally observed, we think that this fact might depend on kinetic factors which are modulated by the interplay between the less destabilizing nature of bromide toward phosphorus (the *trans*–influence of bromide being lower than that of iodide) and the higher stability of the undistorted chelating ring of the DPPQ. More simply, it could just be the intrinsic uncertainty typical of this sort of calculation.

Crystal Structure Determination

An ORTEP ¹⁶ view of the neutral complex 2a is shown in Fig.1. A selection of bond distances and angles is given in Table 2SI. The geometry around the Pd centre is a slightly distorted square planar. The four positions around the central Pd are occupied by the carbon C_{α} of the 1, 2, 3, 4–tetrakis(methoxycarbonyl) buta–1, 3–diene–4–Br–1–yl anionic ligand, a Br anion, the pyridine nitrogen and phosphorus of the 8-diphenylphosphanyl-quinoline (DPPQ) ligand. The deviations from the basal plane are: – 0.0004(4) for Br1, 0.016(3) for N1, – 0.021(1) for P1 and 0.022(3) Å for

C22. Pd1 is situated at 0.0662(3) Å above this average plane. The C22=C23-C24=C25 buta-1, 3-diene moiety displays an *anti-clinal* conformation with a torsion angle of -117.0(4)°. An ORTEP ¹⁶ view of the neutral isostructural complexes **4b** and **5b** is shown in Figs 2 and 4. A selection of bond distances and angles is given in Table 2SI. In both complexes, the geometry around the Pd centre is square planar distorted towards a tetrahedral arrangement. The four positions around the central Pd are occupied by halogen atoms, Br in **4b** or I in **5b**. The pyridine nitrogen of the 8-diphenylphosphanyl-2-methyl-quinoline (DPPQ-Me) ligand and the α, δ-carbons of the buta-1, 3-diene-4-Br(or I)-1-yl moiety of the ligand are as in the previous complex **2a**. The deviations of the four atoms from the basal plane are: – 0.0053(5) for Br1, 0.224(3) for N1, – 0.273(3) for C23 and 0.285(3) Å for C26 with Pd1 atom 0.0975(3) Å above this average plane, in complex **4b**. For complex **5b** they are: – 0.0019(3) for I1, 0.222(3) for N1, – 0.333(3) for C23 and 0.289(3) Å for C26 with the Pd1 atom 0.1228(3) Å above this average plane, in complex **5b**. In both complexes the Pd1-C23-C24-C25-C26 palladacyclopentene rings are approximately planar with maximum deviations from the mean planes of – 0.081(4) for C25 and 0.074(3) Å for C26 in complex **4b** and – 0.072(3) for C25 and 0.058(3)Å for C26 in complex **5b**.

The different coordination mode of the buta-1, 3-diene ligand in complexes **4b** and **5b** with respect to that observed in complex **2a** gives rise to variations both in Carbon hybridisations and in C-C bond distances.

Conclusions

The oxidative addition of Br_2 or I_2 to palladacyclopentadienyl complexes bearing the bidentate DPPQ or DPPQ-Me as spectator ligands yields different derivatives depending on the nature of the ancillary ligands and halogens. Thus, complex 1a reacts with Br_2 yielding the σ -butadienyl derivative 2a and complex 1b with I_2 to give the unprecedented zwitterionic complex 5b, only. The cross reactivity yields in both cases an equilibrium mixture of the σ -butadienyl and zwitterionic complexes 2b and 4b (case of complex 1b reacting with Br_2) and 3a and 5a (case of complex 1a reacting with I_2). The experimental results and in particular the reactivity of the butadienyl derivatives were interpreted taking into account the different lability of the bidentate ligands (DPPQ-Me which is more labile than DPPQ), the higher *trans*-influence of Γ compared to Br^- , and the charge density on the butadienyl sp^2 carbon which is modulated by the electronegativity of the bound halide. In order to give an adequate support to the experimental observations a detailed computational study, the solid state structure of complexes sp_1 and sp_2 to the determination of the reaction rates characterizing the equilibrium reaction between sp_2 and sp_3 were also carried out.

Experimental

Solvents and Reagents

All the following distillation processes were carried out under inert atmosphere (Argon). Acetone and CH₂Cl₂ were distilled over 4Å molecular sieves and CaH₂ respectively. All the other chemicals were commercially available grade products and were used as purchased.

Data Analysis. Non linear analysis of the data related to equilibrium and kinetics measurements were performed by locally adapted routines written in the SCIENTIST[®] environment.

IR and NMR Measurements

The IR, ¹H, ¹³C and ³¹P NMR spectra were recorded on a Perkin-Elmer Spectrum One spectrophotometer and on a Bruker 300 Avance spectrometer, respectively.

Computational Details

The geometrical optimization of the complexes was carried out without symmetry constraints, using the hyper-GGA functional M06 22,23 in combination with polarized triple– ζ –quality basis sets (LAN2TZ(f)) 24,25 and relativistic pseudopotential for the Pd atoms, a polarized double– ζ –quality basis sets (LANL2DZdp) 26 with diffuse functions for the halogen atoms and a polarized double– ζ –quality basis sets (6-31G(d,p)) for the other elements.

Solvent effects (dichloromethane, $\varepsilon = 8.93$) were included using CPCM ^{27, 28}.

The "restricted" formalism was applied in all the calculations. By means of the stationary points characterized by IR simulation, the zero–point vibrational energies and thermodynamic parameters were obtained. ²⁹

The software used was Gaussian '09 21 and all the computational work was carried out on Intel based x 86–64 workstations.

Crystal Structure Determinations

The crystal data of compounds **2a**, **4b** and **5b** were collected at room temperature using a Nonius Kappa CCD diffractometer with graphite monochromated Mo-Kα radiation. The data sets were integrated with the Denzo–SMN package ³⁰ and corrected for Lorentz, polarization and absorption effects (SORTAV) ³¹. The structures were solved by direct methods using the SIR97 ³² system of programs and refined using full–matrix least–squares with all non–hydrogen atoms anisotropically and hydrogens included on calculated positions, riding on their carrier atoms.

All calculations were performed using SHELXL-97 ³³ and PARST ³⁴ implemented in WINGX ³⁵ system of programs. The crystal data are given in Table 3SI.

Crystallographic data have been deposited at the Cambridge Crystallographic Data Centre and allocated the deposition numbers CCDC 1053523, 1053524, 1053525. These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html or on application to CCDC, Union Road, Cambridge, CB2 1EZ, UK [fax: (+44)1223-336033, e-mail: deposit@ccdc.cam.ac.uk]

Synthesis of the Ligands and Starting Complex

The ligands DPPQ, ¹² DPPQ–Me ¹³ and the polymeric complex [PdC₄(COOMe)₄]_n ¹⁵ were synthesized according to published procedures.

Synthesis of Complex 1a

In a two necked 100 ml flask 198.0 mg (0.51 mmol) of $[PdC_4(COOMe)_4]_n$ and 172.2 mg (0.55 mmol) of DPPQ were dissolved in 20 ml of anhydrous acetone under inert atmosphere (Ar). The resulting solution was stirred for 1 h and concentrated under vacuum to a reduced volume (2– 3 ml). Dropwise addition of diethyl ether (5– 10 ml) causes the precipitation of the 309.2 mg (87% yield) of the title complex as a yellow–orange microcrystalline product which was filtered off on a gooch filter, carefully washed with diethyl ether and n–pentane and dried under vacuum.

¹H–NMR (300 MHz, CDCl₃, T = 298 K, ppm) δ: 2.77 (s, 3H, OCH₃), 3.64 (s, 3H, OCH₃), 3.71 (s, 3H, OCH₃), 3.73 (s, 3H, OCH₃), 7.39-7.61 (m, 8H, H³, Ph), 7.64 (ddd, 1H, J = 7.7, 7.2, 1.2 Hz, H⁶), 7.66-7.77 (m, 4H, H⁵, Ph), 7.98 (d, 1H, J = 7.9 Hz, H⁷), 8.37 (dt, 1H, J = 8.5, 1.4 Hz, H⁴), 9.06 (dd, 1H, J = 5.0, 1.4 Hz, H²).

 $^{31}P\{^{1}H\}$ -NMR (CDCl₃, T = 298 K, ppm) δ : 33.4.

¹³C{¹H }-NMR (CDCl₃, T = 298 K, ppm) δ: 50.5 (CH₃, OCH₃), 50.9 (CH₃, OCH₃), 51.2 (CH₃, OCH₃), 51.3 (CH₃, OCH₃), 122.6 (CH, C³), 127.8 (d, CH, J_{CP} = 5.5 Hz, C⁶), 129.3 (d, C, J_{CP} = 7.8 Hz, C¹⁰), 131.1 (CH, C⁵), 135.9 (d, C, J_{CP} = 41.7 Hz, C⁸), 136.1 (CH, C⁷), 139.0 (CH, C⁴), 143.2 (C, C=C), 150.1 (C, C=C), 150.9 (d,C, J_{CP} = 21.6 Hz, C⁹), 154.9 (CH, C²), 157.2 (d, C, J_{CP} = 7.5 Hz, C=C), 164.1 (C, C=O), 165.3 (C, C=O), 173.1 (d, C, J_{CP} = 8.0 Hz, C=O), 175.4 (d, C, J_{CP} = 7.4 Hz, C=O), 176.7 (C, C=C).

Anal. Calcd for C₃₃H₂₈NO₈PPd: C 56.30, H 4.01, N 1.99. Found: C 56.41, H 4.18, N 1.87.

Synthesis of Complex 1b

Complex **1b** was obtained following the same procedure as for complex **1a**. A yellow-orange microcrystalline solid was obtained with a 74% yield.

¹H–NMR (300 MHz, CDCl₃, T = 298 K, ppm) δ : 3.39 (s, 3H, quinoline-CH₃), 3.68 (s, 3H, OCH₃), 3.64 (s, 3H, OCH₃), 2.89 (s, 3H, OCH₃), 2.86 (s, 3H, OCH₃); 7.89 (d, 1H, H³, J = 9 Hz), 8.18 (d, 1H, H⁴, J = 9 Hz); 7.42 (m, 10H).

 $^{31}P\{^{1}H\}$ -NMR (CDCl₃, T = 298 K, ppm) δ : 30.16.

Anal. Calcd for C₃₄H₃₀NO₈PPd: C 56.88, H 4.21, N 1.95. Found: C 56.94, H 4.07, N 1.89.

Synthesis of Complex 2a

In a two necked 50 ml flask, to 71.1 mg (0.10 mmol) of compound 1 dissolved in 10 ml of anhydrous CH_2Cl_2 17.8 mg (0.111 mmol) of Br_2 dissolved in 5 ml of CH_2Cl_2 were added under an inert atmosphere (Ar). The reaction mixture immediately decolorizes and after 5 min stirring the solution was evaporated under vacuum to 3 – 4 ml. The dropwise addition of diethyl ether induces the precipitation of the title complex as a yellow microcrystalline solid. The solid was filtered off on a gooch filter, washed several times with diethyl ether and n-pentane and dried under vacuum to obtain 81.7 mg (94% yield) of the complex.

¹H–NMR (300 MHz, CDCl₃, T = 298 K, ppm) δ: 3.41 (s, 3H, OCH₃), 3.63 (s, 3H, OCH₃), 3.72 (s, 3H, OCH₃), 3.74 (s, 3H, OCH₃), 7.37-7.54 (m, 6H, Ph), 7.65-7.70 (m, 2H, H³, H⁶), 7.82-7.98 (m, 4H, H⁷, Ph), 8.05 (d, 1H, J = 8.0 Hz, H⁵), 8.43 (dt, 1H, J = 8.3, 1.5 Hz, H⁴), 10.47 (dd, 1H, J = 51, 1.5 Hz, H²).

 $^{31}P\{^{1}H\}$ -NMR (CDCl₃, T = 298 K, ppm) δ : 34.3.

¹³C {¹H}-NMR (CDCl₃, T = 298 K, ppm) δ: 51.3 (CH₃, OCH₃), 52.0 (CH₃, OCH₃), 53.2 (CH₃, OCH₃), 53.3 (CH₃, OCH₃), 120.9 (C, C=CBr), 123.4 (CH, C³), 127.9 (d, CH, J_{CP} = 6.9 Hz, C⁶), 129.6 (d, C, J_{CP} = 9.4 Hz, C¹⁰), 130.4 (C, C=C), 131.8 (CH, C⁵), 134.4 (d, C, J_{CP} = 44.3 Hz, C⁸), 137.0 (CH, C⁷), 139.0 (CH, C⁴), 142.7 (C, C=C), 150.2 (d,C, J_{CP} = 20.2 Hz C⁹), 156.4 (CH, C²), 161.8 (C, C=O), 162.5 (C, C=C), 162.9 (C, C=O), 166.3 (C, C=O), 171.4 (d, C, J_{CP} = 2.6 Hz, C=O). IR(KBr pellets): $v_{C=O}$ 1709 cm⁻¹.

Anal. Calcd for C₃₃H₂₈Br₂NO₈PPd: C 45.89, H 3.27, N 1.62. Found: C 45.73, H 3.18, N 1.54.

Synthesis of Complex 2b

Complex **3a** was obtained following similar conditions to complex **2a** but the synthesis was carried out at a low temperature (273 K) and the complex was collected within 10'.

A pale-yellow microcrystalline solid was obtained with a 61% yield.

¹H–NMR (300 MHz, CDCl₃, T = 298 K, ppm) δ: 3.32 (s, 3H, quinoline-CH₃), 3.45 (s, 3H, OCH₃), 3.60 (s, 3H, OCH₃), 3.87 (s, 3H, OCH₃), 3.88 (s, 3H, OCH₃), 7.34–7.62 (m, 9H, PPh₂, H³), 7.76–8.04 (m, 5H, H⁵, H⁶, H⁷, PPh₂), 8.14 (dd, 1H, J= 8.5, 1.6 Hz, H⁴).

 $^{31}P\{^{1}H\}-NMR (CDCl_{3}, T = 298 \text{ K, ppm}) \delta: 34.3.$

IR (KBr pellets): $v_{C=0}$ 1732, 1716 and 1704 cm⁻¹.

Anal. Calcd for C₃₃H₂₈I₂NO₈PPd: C 41.38, H 2.95, N 1.46. Found: C 41.21, H 2.97, N 1.32.

Synthesis of Complex 4b

Complex 4b was obtained by reacting complex 1b and Br_2 under the same experimental condition described above in the case of complex 2a. The reaction mixture was stirred for 28 h and the reaction product precipitated by addition of diethyl ether.

A yellow microcrystalline solid was obtained with a 78% yield.

¹H–NMR (300 MHz, CDCl₃, T = 298 K, ppm) δ: 3.31 (s, 3H, OCH₃), 3.42 (s, 3H, OCH₃), 3.54 (s, 3H, quinoline-CH₃), 3.64 (s, 3H, OCH₃), 3.71 (s, 3H, OCH₃), 7.39-7.62 (m, 9H, PPh₂, H³, H⁷), 7.67-7.81 (m, 3H, H⁶, PPh₂), 7.95-8.08 (m, 2H, H⁵, PPh₂), 8.28 (dd, 1H, J = 8.5, 1.9 Hz, H⁴).

³¹P{¹H}–NMR (CDCl₃, T = 298 K, ppm) δ: 10.7.

¹³C{¹H}-NMR (CDCl₃, T = 298 K, ppm) δ: 30.8 (CH₃, quinoline-CH₃), 31.2 (C, Pd-C- Br), 41.7 (d, C, J_{CP} = 59.9 Hz, C-PPh₃), 51.9 (CH₃, OCH₃), 52.0 (CH₃, OCH₃), 52.1 (CH₃, OCH₃), 52.4 (CH₃, OCH₃), 124.9 (CH, C³), 127.4 (d, C, J_{CP} = 7.0 Hz, C¹⁰), 130.5 (d, C, J_{CP} = 65.9 Hz, C⁸), 132.4 (CH, C⁶), 133.9 (CH, C⁵), 137.7 (C, C=C), 138.6 (CH, C⁴), 140.4 (d, CH, J_{CP} = 11.4 Hz, C⁷), 148.3 (d, C, J_{CP} = 3.0 Hz, C⁹), 157.9 (d, C, J_{CP} = 11.5 Hz, C=C), 157.9 (C, C=O), 164.4 (CH, C²), 166.5 (C, C=O), 170.3 (d, C, J_{CP} = 7.9 Hz, C=O), 171.4 (C, C=O).

IR (KBr pellets): $v_{C=0}$ 1722 cm⁻¹.

Anal. Calcd for C₃₄H₃₀Br₂NO₈PPd·CH₂Cl₂: C 43.66, H 3.35, N 1.45. Found: C 43.51, H 3.23, N 1.32.

Synthesis of Complex 5b

Complex 5b was obtained by reacting complex 1b and I_2 under the same experimental conditions as described above. The reaction mixture was stirred for 10 min and the reaction product precipitated by addition of diethyl ether.

A pale–yellow microcrystalline solid was obtained in 93% yield.

¹H–NMR (300 MHz, CDCl₃, T = 298 K, ppm) δ: 3.24 (s, 3H, OCH₃), 3.43 (s, 3H, OCH₃), 3.61 (s, 3H, quinoline–CH₃), 3.63 (s, 3H, OCH₃), 3.74 (s, 3H, OCH₃), 7.39-7.80 (m, 12H, PPh₂, H³, H⁷, H⁶, PPh₂), 7.98–8.05 (m, 2H, PPh₂), 8.15 (dt, 1H, J = 7.1, 2.3 Hz, H⁵), 8.34 (dd, 1H, J = 8.5, 1.9 Hz, H⁴).

 $^{31}P\{^{1}H\}-NMR (CDCl_{3}, T = 298 \text{ K, ppm}) \delta: 8.9.$

¹³C{¹H}-NMR (CDCl₃, T = 298 K, ppm) δ: 32.9 (C, Pd-C-I), 33.6 (CH₃, quinoline-CH₃), 43.8 (d, C, J_{CP} = 61.8 Hz, C-PPh₃), 52.1 (CH₃, OCH₃), 52.2 (CH₃, OCH₃), 52.3 (CH₃, OCH₃), 52.4 (CH₃, OCH₃), 124.7 (CH, C³), 127.9 (d, C, J_{CP} = 7.0 Hz, C¹⁰), 131.3 (d, C, J_{CP} = 66.8 Hz, C⁸), 132.4 (CH, C⁶), 134.2 (CH, C⁵), 135.5 (C, C=C), 139.2 (CH, C⁴), 140.8 (d, CH, J_{CP} = 11.0 Hz, C⁷), 148.9 (d, C, J_{CP} = 3.0 Hz, C⁹), 161.4 (d, C, J_{CP} = 10.5 Hz, C=C), 164.4 (CH, C²), 165.0 (C, C=O), 166.2 (C, C=O), 169.5 (d, C, J_{CP} = 7.2 Hz, C=O), 171.6 (C, C=O).

IR (KBr pellets): $v_{C=O}$ 1718 cm⁻¹.

Anal. Calcd for C₃₄H₃₀I₂NO₈PPd·CH₂Cl₂: C 39.78, H 3.05, N 1.33. Found: C 39.651, H 2.97, N 1.19.

Supplementary information available

Further details of the structure determination, final coordinates, bond distances and bond angles and ORTEP representations for **2a**, **4b** and **5b**, NMR spectra, schematic computational outcomes.

- [17] Thanks to the reduced solubility of the zwitterionic complex **4b** in CH₂Cl₂ compared to that of complex **2b**, it was possible to separate crystals for diffractometric determination from the equilibrium mixture. On the contrary, any attempts at separating suitable crystals of complex **2b** were unsuccessful since only some crystals of complex **4b** were obtained after about a week at 263 K.
- [18] As can be seen in Fig. 3 the starting concentration (t=0) of complex **4b** is not null (the estimated values ensuing from the regression analysis are [**2b**] = $8.8 \times 10^{-3} \pm 4 \times 10^{-6}$, [**4b**] =1.16 $\times 10^{-3} \pm 4 \times 10^{-6}$). Since the reaction was carried out starting from an authentic sample of **2b** which was isolated pure some days before the NMR study, we think that the interconversion reaction is also likely to occur in the solid state.
