This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
Palladium(II) mononuclear and palladium(II)/ruthenium(II) heterodinuclear complexes containing 2-quinolyl-substituted (pyridine-2-carbonyl)hydrazone

Asami Mori, Takayoshi Suzuki, Yuichi Nakatani, Yukinari Sunatsuki, Masaaki Kojima and Kiyohiko Nakajima

A reaction of [PdCl₂(cod)] (cod = 1,5-cyclooctadiene) and an E/Z mixture of quinoline-2-carbaldehyde (pyridine-2-carbonyl)hydrazone (HL) gave two kinds of Pd(II) mononuclear complexes, [PdCl₂(Z-L⁻κ₃N,N',N'')] (1) and [PdCl₂(E-HL⁻κ₂N,N'')] (2), where L⁻ is the deprotonated hydrazonate anion and HL⁺ is the quinolinium–hydrazonate zwitterionic form of HL. Complex 2 is gradually converted to 1 in solution, and complex 1 is a good precursor to prepare a Pd(II)/Ru(II) heterodinuclear complex bridged by the hydrazonate, trans(Cl,Cl)-[RuCl₂(PPh₃)₂(µ-L)PdCl] (3).

2-Picolinoylhydrazones having a coordinating substituent at the C(imine) atom (Scheme 1) are promising ligands for stepwise and highly selective construction of hetereometallic di- or polynuclear complexes, because they have some different types of donor groups in a molecule. In addition, the hydrazone NH group is capable of deprotonation and reprotonation by the external pH control when the hydrazone coordinates to a metal ion via the imine-N atom, which would be advantageous to the rational and stepwise synthesis of heterometallic complexes. However, synthetic studies for such heterometallic complexes with hydrazones or hydrazonates are still limited. To the best of our knowledge, only a few examples with cyclic tetranuclear structures have been reported, although they were prepared either by a one-pod reaction or by stepwise complexations. Recently, we prepared mononuclear Ru(III) complexes with quinoly-2-carbonylhydrazone, HL (Scheme 1), and a series of heterodimetallic Ru(III)–M(II) (M = Mn, Fe, Co, Ni, Cu and Zn) complexes bridged by the hydrazonate, L⁻. Upon dinculation reaction of trans(P,P)-[RuCl₂(PPh₃)₂(HL-κN(imine),κO(amide))] with 3d-metal chloride (MCl₂), deprotonation from the hydrazone moiety and oxidation of the Ru centre (to Ru(III)) occurred simultaneously. However, the Ru(II)–hydrazone complex could not react with typical Pd(II) chloride precursors, e.g., [PdCl₂(cod)] or [PdCl₂(PhCN)₂]. Therefore, in order to synthesize heterodinmetallic Ru–Pd complexes with a bridging L⁻ by a different strategy, mononuclear Pd(II) complexes containing HL or its anion are attempted to prepare in advance of the reaction with Ru(II) precursor complexes.

The ligand, HL, was obtained as a 58:42 mixture of the E and Z isomers by a reaction of 2-picolylhydrazine and 2-quinolylaldehyde. When an equimolar (0.35 mmol) mixture of [PdCl₂(cod)], an E/Z mixture of HL and NEt₃ in acetonitrile (15 cm³) was allowed to stand at room temperature for several days, orange crystals of complex 1•0.5CH₃CN were deposited in a nearly quantitative (96%) yield (Scheme 2a). The crystal structure of...
Figure 1 ORTEPs (50% probability level) of (a) [PdCl(Z-L-κN(pyridine),κN(hydrazonato),κN(quinoline)]) in 1•0.5CH3CN, (b) [PdCl2(E-HL-κN(pyridine),κN(hydrazonato)]) in 2•0.5CH3CN•H2O and (c) the heterodinuclear complex in trans(Cl,Ct)[RuCl2(PPh3)2(μ-L)PdCl]•2CH2Cl2 (3•2CH2Cl2; H atoms omitted for clarity).

1•0.5CH3CN was revealed by X-ray analysis, and a perspective drawing of 1 is shown in Figure 1a. It is obvious that the hydrazone having a Z-form is deprotonated to act as a tridentate ligand to a PdII center in the κ2N(pyridine),N(hydrazonato),N(quinoline) mode.

The Pd1–Cl1 bond length in 1, [PdCl(Z-L-κN,N,N′,N″)]Cl, is 2.3359(6) Å (Table S2), which is slightly longer than those in [PdCl(terpy)]1 (terpy = 2,2′:6′,2″-terpyridine) complexes (2.29–2.30 Å). Among three Pd–N bonds in 1, the Pd1–N3(hydrazonato), 1.967(2) Å, is a little shorter than the others, 2.044(2) Å for Pd1–N1(quinoline) and 2.036(2) Å for Pd1–N4(pyridine). However, a similar bond shortening of the central Pd–N bond was also observed in the above terpy complexes. Thus, it is concluded that the anionic hydrazonato-N donor gives a stronger trans influence on the trans-positions Cl− ligand than a neutral pyridine-N donor. Another remarkable feature in the molecular structure of complex 1 is a large twist of the intrinsically planar hydrazonato ligand, Z-L. The coordination geometry around the PdII centre is almost square-planar, as the CI1–Pd1–N3 and N1–Pd1–N4 bond angles are 168.85(6)° and 171.20(7)°, respectively, and the τ value indicating a tetrahedral distortion is 0.14. In contrast, in the ligand of Z-L the dihedral angle between the carboxylic acid hydrazine (CAH; −C(O)−N−H) and the quinoline planes and that between the CAH and the pyridine planes are 27.0(1)° and 15.9(1)°, respectively (Table S2). This distortion could be originated from the steric interaction between the coordinated Cl1 ligand and the H atom bound to C2 in the quinoline group.

The formation of complex 1 in nearly quantitative yield indicated that the E to Z isomerization, as well as the deprotonation, of HL took place during the reaction with [PdCl2(cod)]. As mentioned in our previous paper, the hydrazone itself did not isomerize to each other under a similar condition in the presence of NEt3. This result suggests that the PdII ion assists (or catalyzes) the E to Z conversion of the ligand. Then, we have examined a reaction of [PdCl2(cod)] and an E/Z mixture of HL in acetonitrile without addition of NEt3. After standing the reaction mixture at room temperature overnight, yellow needle or thin platelet crystals of 2•0.5CH3CN•H2O were deposited, together with orange crystals of complex 1•0.5CH3CN (Scheme 2b).

The X-ray analysis for 2•0.5CH3CN•H2O indicated that it contains the coordinated hydrazone in the E-form with a zwitterionic character having the hydrazonate and quinolinium moieties (HL′). The molecular structure of [PdCl2(E-HL′)]Cl is depicted in Figure 1b, which is a typical square-planar PdII complex with two Cl−ligands in the cis position. The hydrazonate coordinates with a bidentate κ2N(pyridine),N(hydrazonato) mode to form a planar five-membered chelate ring. The dihedral angle between the CAH and the quinoline planes and that between the CAH and the pyridine planes are 2.3(1) and 2.4(1)°, respectively. This planarity indicates that the π-electrons of HL′ in complex 2 delocalize over the whole ligand moiety. The Pd1–Cl1 and Pd1–Cl2 bond lengths are 2.296(1) and 2.315(1) Å, respectively, and not so much different from each other. The Pd1–N3 bond, 2.071(3) Å, is longer than the Pd1–N4 bond, 2.020(3) Å, which is a remarkable contrast to the corresponding bond lengths in complex 1. A similar tendency of the Pd–N bond lengths for the bidentate and tridentate hydrazonato ligands was observed in the related complexes.

An acetonitrile solution of complex 2 exhibited a gradual spectral change as shown in Figure 2a, and the converged spectrum (after 2 h at room temperature) was quite similar to the spectrum of 1 (Figure S1). This fact indicates that the E-isomer of the zwitterionic hydrazine (HL′) bound to a PdII ion isomerizes to the Z-isomer without addition of any base. In other words, complex 2 is a kinetically preferable product from [PdCl2(cod)] and HL, and is gradually converted to the thermodynamically more stable complex 1 in solution (Scheme 2c).

Here, it is noted that the formation of complexes 1 and 2 by a reaction of [PdCl2(cod)] and (a mixture of Z- and E-isomers of) HL is not straightforward, because in both complexes the ligand coordinates to a PdII ion via the hydrazonato-N atom. It is well-known that the hydrazone N–H itself is not acidic; however, when the hydrazonate coordinates to a metal ion through the imine-N atom, it becomes highly acidic to induce easy deprotonation. Thus, it is speculated that at the initial stage of reaction a coordinative interaction to a PdII ion would occur via the imine-N donor of HL. The deprotonation from the hydrazonate N–H, followed by migration of the Pd1 fragment, would give a complex of [PdCl2Z− or E-L-κ2N(pyridine),N(hydrazonato)]+ Then, in order to crystallize the
mononuclear Ru[RuCl₂(PPh₃)₃] to prepare a heterometallic Pd–Ru complex. Moreover, one of the resultant Ruᴵᴵ complexes, trans(P,P){[RuCl₂(PPh₃)₃]HL]}, reacted with first-row transition-metal chlorides (MC₁; M = Mn, Fe, Co, Ni, Cu and Zn) to give the hydrazone-bridged Ruᴵᴵ–M complexes, trans(P,P){[RuCl₂(PPh₃)₃]HL}MC₁.⁵ Thus, a reaction of complex 1 with [RuCl₂(PPh₃)₃] was examined to prepare a heterometallic Pd–Ru complex.

Complex 1 was reacted with an equimolar amount of [RuCl₂(PPh₃)₃] in dichloromethane under an argon atmosphere for 3 h at room temperature, and a green precipitate of the product (complex 3) was obtained in a nearly quantitative (~98%) yield after evaporation of the solvent under reduced pressure, followed by addition of hexane into the concentrate (Scheme 2d). Single crystals of 3·2CH₂Cl₂ suitable for X-ray analysis were deposited by slow diffusion of layered hexane into a dichloromethane solution. The analysis revealed that there are one dinuclear complex and two dichloromethane molecules in an asymmetric unit of a triclinic lattice with a space group P-1.

The molecular structure of complex 3 is illustrated in Figure 1c, and selected bond lengths and angles are summarized in Table S2. It is obvious that 1 successfully acts as a complex ligand to bind a RuCl₂(PPh₃)₃ fragment in a bidentate κ²N(imine),κ₁O(amide) coordination mode. The structural parameters around the Pd center in 3 are almost unchanged from those in complex 1, although the ligand twisting is slightly reduced in the dinuclear complex 3. The coordination geometry around the Ru center is trans(Cl,Cl) configuration, which is the same as that of the kinetically formed mononuclear complex, trans(Cl,Cl){[RuCl₂(PPh₃)₃]HL} (4), and the coordination bond lengths around the Ru center in 3 are very similar to those in 4.⁴ Thus, it is concluded that the oxidation states of the metal centers in complex 3 are assigned as Pdᴵᴵ–Ruᴵᴵ.

The ³¹P NMR spectrum of 3 in CDCl₃ showed two doublet signals at δ 47.3 and 37.9 with J₁,p = 35 Hz, which is very similar to the spectrum of complex 4 and coincides with the molecular structure of dinuclear Pdᴵᴵ–Ruᴵᴵ complex determined by the single-crystal X-ray analysis. The redox potential of Ruᴵᴵᴵ/H⁺ couples in complex 3 was observed at 142 mV vs. Fc⁺/Fc (Figure S2), which is almost the same as that in complex 4 (118 mV vs. Fc⁺/Fc).⁶ It was also reported that complex 4 is a kinetically favourable product and exhibited a thermal conversion in solution due to an exchange of the coordinated Cl⁻ and PPh₃ ligands.⁷ The heterometallic Pdᴵᴵ–Ruᴵᴵ complex 3 showed a very similar UV-vis spectral change in dichloromethane (Figure 2b), and the converged product (in CDCl₃) exhibited two doublet ³¹P NMR signals at δ 45.3 and 40.7 (J₁,p = 35 Hz) (Figure S3). Although the crystal structure of the product has not been determined yet, the observed spectroscopic features suggested that the geometrical isomerization around the Ruᴵᴵ centre would also take place in this heterometallic complex.

In conclusion, we have prepared two kinds of mononuclear Pdᴵᴵ complexes by a reaction of [PdCl₃(cod)] and an E/Z mixture of the hydrazone, HL. One is dichlorido complex, [PdCl₂(E-HL³)] (2), in which the zwitterionic HL³ is coordinated through the pyridine-N and hydrazone-N to act as a bidentate ligand. The other is [PdCl₂(Z-L)] (1), where an anionic hydrazone (L⁻) is ligating through the pyridine-N, hydrazone-N and quinoline-N to act as a tridentate ligand. It was also found that complex 2 in solution was gradually converted to the thermodynamically more stable complex 1. In addition, complex 1 reacted with [RuCl₂(PPh₃)₃], affording a heterometallic complex, trans(Cl,Cl)-[CIPd(μ-L)RuCl₂(PPh₃)₃] (3) in a high selectivity. In complex 3 the oxidation state of the Ru centre is assigned as Ruᴵ, which is in contrast to the previously reported Ruᴵᴵ–M³ (M = Mn, Fe, Co, Ni, Cu and Zn) complexes with the same bridging mode of hydrazone, L⁻. Complex 3 showed a similar thermal conversion to the mononuclear Ruᴵ hydrazone complex 4. The characterization of the converged products, as well as the investigation of the physical and chemical functionalities and catalytic abilities of the reported hydrazone complexes, are now in progress in our laboratory.
