Accepted Manuscript

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this *Accepted Manuscript* with the edited and formatted *Advance Article* as soon as it is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

Graphical Abstract

We have synthesized β -octachloro-*meso*-tetraphenylporphyrinatooxidovanadium(IV) (VOTPPCl₈) and characterized. It exhibited highly nonplanar electron deficient porphyrin core having very high thermal stability. Further, it was utilized for selective epoxidation of olefins in good yields with very high TOF numbers (6566-9650 h⁻¹).

We have synthesized 2,3,7,8,12,13,17,18-octachloro-*meso*-tetraphenylporphyrinatooxidovanadium(IV) (VOTPPCl₈) and characterized by various spectroscopic (UV-Vis, IR and EPR) techniques, MALDI-TOF mass spectrometry and elemental analysis. DFT optimized structure of VOTPPCl₈ in CH₃CN exhibited severe nonplanar saddle shape conformation of porphyrin macrocycle. Cyclic voltammogram of VOTPPCl₈ showed 500 mV anodic shift in first ring reduction and 220 mV in first ring oxidation potentials as compared to VOTPP indicating the electron deficient nature of porphyrin π -system and further proves the existence of nonplanar conformation of the macrocycle in solution. Further, VOTPPCl₈ exhibited very high thermal stability till 390 °C as indicated in its thermogram. The oxidation state of metal ion (V^{IV}) was confirmed by EPR spectroscopy and VOTPPCl₈ exhibited axial spectrum which corresponds to axially compressed d_{xy}¹ configuration. VOTPPCl₈ was utilised for the selective epoxidation of various olefins in good yields with very high TOF numbers (6566-9650 h⁻¹) in presence of H₂O₂ as an oxidant and NaHCO₃ as promoter in CH₃CN/H₂O mixture. The oxidoperoxidovanadium(V) species is expected to be the intermediate during the catalytic reaction which is probed by ⁵¹V NMR spectroscopy and MALDI-TOF mass analysis. Notably, VOTPPCl₈ is stable after catalytic reaction and doesn't form μ -oxo dimer due to highly electron deficient nonplanar porphyrin core and can be reused for several cycles.

Selective oxidation of olefins to epoxy compounds has always been an interesting area of research for the chemists owing to their great importance in the production of highly valued commodity chemicals such as polyurethanes, unsaturated resins, glycols, surfactants, and other products.¹ Transition metal complexes play a vital catalytic role in various organic transformations e.g. epoxidation, hydroxylation, C-H activation, hydrogenation, polymerisation, carbon-carbon coupling reactions, halogenation, dehalogenation and so on in homogeneous and heterogeneous media.^{2,3} Among them, metalloporphyrins have been found to be efficient catalysts for alkene epoxidation using various oxygen atom donors^{4,5} due to their high chemical and thermal stability, interesting physicochemical properties, strong absorption in the visible region and flexible architectural modification to tailor redox properties and conformational features. Apart from catalysis, they were widely utilized in dye-sensitised solar cells (DSSCs),⁶ photodynamic therapy (PDT),⁷ anion sensing⁸ and nonlinear optical studies.⁹ The β -functionalization of *meso*-tetraphenylporphyrin (TPP) is of great interest since the electronic properties of the porphyrin π -system can be altered by tuning the size, shape and electronic nature of the β -substituents¹⁰ as compared to the substituents at the *meso*-

aryl positions.

Iron and manganese porphyrin complexes were widely utilized as effective homogenous catalysts for such oxygenation reactions in last few decades.^{2-3,11} The major drawbacks of homogenous MTPP-based catalysts are (i) the macrocyclic ring is liable for oxidative self-destruction; (ii) aggregation of metalloporphyrins through π - π interactions; (iii) lower turnover frequency (TOF) and; (iv) poor product selectivity. Recently, highly efficient and stable Mn^{III}porphyrinic framework (MOF) was demonstrated for selective epoxidation of olefins in heterogeneous media.¹² Among various metalloporphyrins, vanadyl (V^{IV}O) porphyrins merit special attention owing to their use as anti-HIV agents¹³ as compared to other vanadium complexes as potential therapeutics,¹⁴ 3D supramolecular assemblies¹⁵ and catalysts for oxidation reactions.¹⁵⁻¹⁶ Notably, VOTPP was utilised for oxidation of cyclohexene under homogeneous¹⁶ and heterogeneous conditions,¹⁷ respectively, leading to mixture products (viz. epoxide, alcohol and ketone) with very low TOF. So, there is a quest for highly efficient vanadylporphyrin catalyst for selective oxidation of olefins. Besides dioxygen, aqueous H₂O₂ is the most widely used oxidant since it is inexpensive, environmentally benign and biologically important nature.¹⁸⁻²⁰ The use of NaHCO₃ as promoter and H₂O₂ as a terminal oxidant has been evolved as a highly efficient method for epoxidation of olefins catalyzed by W, Mo and Mn complexes.^{18-19,21-22} H₂O₂ and HCO₃⁻ are used together to increase the activity of H₂O₂ by *in situ* generation of peroxy monocarbonate ion which is more nucleophilic than H₂O₂ and thus attributes to the enhanced

oxidizing activity of the metal complexes.¹⁸⁻²² To the best of our knowledge, there is no report on selective epoxidation of olefins in almost quantitative yields catalyzed by oxidovanadium porphyrin complexes in homogenous media. Herein, we present the selective epoxidation of olefins using biologically important oxidant (i.e., H₂O₂) catalyzed by robust VOTPPCl₈ using NaHCO₃ as promoter with very high turnover frequency (TOF).

Results and Discussion

Synthesis and Characterisation

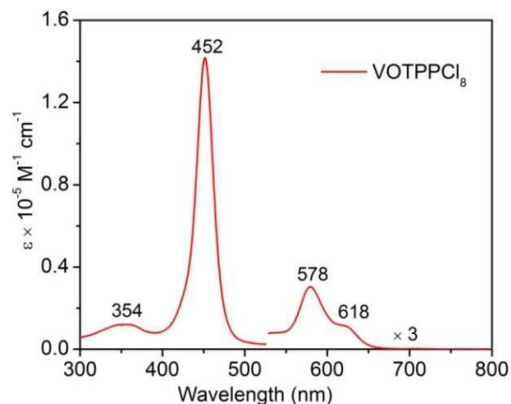

Figure 2. Electronic absorption spectrum of VOTPPCl₈ in CH₂Cl₂ at 298 K.

We have synthesised free base β -octachloro-*meso*-tetraphenylporphyrin (H₂TPPCL₈) using reported procedure.²³ VOTPPCl₈ was prepared by reacting H₂TPPCL₈ with 10 equivalents VOSO₄ in refluxing DMF for 16 hours under argon atmosphere. Then the porphyrin was precipitated by adding excess water, filtered and air dried. The crude porphyrin was purified on silica column using CHCl₃ as eluent. The yield was found to be 79%. In general, our vanadium metallation procedure is much simpler as compared to reported literature methods so far.^{24,15} VOTPPCl₈ was characterised by optical absorption, IR and EPR spectroscopic techniques, mass spectrometry and elemental analysis. Figure 2 represents the UV-Vis spectrum of VOTPPCl₈ in CH₂Cl₂. VOTPPCl₈ exhibited a characteristic UV-Vis spectrum for a metalloporphyrin²⁵ which is blue shifted as compared to that of H₂TPPCL₈. The IR spectrum of H₂TPPCL₈ exhibited a characteristic peak at ν ~3328 cm⁻¹ for NH stretching frequency which disappeared upon metallation and appearance of a new peak at ~1003 cm⁻¹ for V=O stretching confirmed the insertion of VO into the porphyrin core (Figure S1 in the electronic

supporting information (ESI)).¹⁵ Further, the MALDI-TOF mass analysis showed a molecular ion peak at 954.95 (m/z) which is in agreement with the corresponding calculated mass number (m/z = 954.96) as shown in the Figure S2 in the ESI. Our attempts to obtain X-ray quality single crystals were failed. So,

Figure 3. B3LYP/LANLD2Z optimised geometry showing (a) top and (b) side views of VOTPPCl₈ in CH₃CN. In side view, β -chloro and *meso*-phenyl substituents are omitted for clarity.

we have carried out DFT studies using B3LYP functional with LANLD2Z basis set. Figure 3 represent the top and side views of optimised geometries of VOTPPCl₈ in CH₃CN. V^{IV} ion is present in square pyramidal geometry with axial oxido ligand. From the side view (Figure 3b), it is clear that VOTPPCl₈ adopts nonplanar saddle shape conformation due to steric hindrance between peripheral β -chloro and *meso*-phenyl groups.²³ The selected average bond angles and bond lengths of VOTPPCl₈ are listed in table S1 in the ESI. Herein, V^{IV} ion resides 0.515 Å above the porphyrin mean plane formed by 24 atoms core. V=O distance is slightly shorter (1.60 Å) than β -octaethylvanadylporphyrin (1.62 Å).²⁶ Further, VOTPPCl₈ exhibited a large deviation of 24 atoms core ($\Delta 24 = 0.535$ Å) and β -pyrrole carbons, ($\Delta C_{\beta} = \pm 1.128$ Å) from the porphyrin mean plane (Table S1, ESI). This is further supported by longer C _{β} -C _{β} bond length (1.375 Å) and the increment in C _{β} -C _{α} -C _{m} angle (~128°) with the concomitant decrement in the N-C _{α} -C _{m} angle (~123.8°) as compared to reported quasi planar vanadyl porphyrin.²⁶ Furthermore, DFT analysis of free base H₂TPPCL₈ in CH₃CN slightly increases nonplanarity (Figure S3, ESI) as reflected by increment in ΔC_{β} (± 1.185 Å) and $\Delta 24$ (± 0.674 Å) as compared to VOTPPCl₈ (Table S2, ESI). The insertion of vanadyl (VO²⁺) into H₂TPPCL₈ core slightly alters the nonplanarity of the macrocycle.

Figure 4. CV of VOTPPCl₈ (1 mmol) in dichloromethane containing 0.1 M TBAPF₆ at 298 K. Potentials are measured with respect to Ag/AgCl electrode.

Electrochemical studies of VOTPP have been examined in non-aqueous media.²⁷ Figure 4 represents the cyclic voltammogram

(CV) of VOTPPCl₈ which is measured in dichloromethane containing TBAPF₆ as supporting electrolyte at 298 K. It exhibited ring-centred two one electron oxidations and reductions which are further supported by the differential pulse voltammogram (DPV) of VOTPPCl₈ by showing four redox peaks with almost same amplitude (Figure S4, ESI). Notably, VOTPPCl₈ exhibited a remarkable anodic shift ($\Delta E_{red} = 500$ mV) in the first ring reduction as compared to VOTPP whereas in oxidation only 220 mV anodic shift was observed due to nonplanar conformation of macrocycle which destabilizes the HOMOs and makes oxidation easier relative to reduction (Figure S5, ESI).⁹ The anodic shift in redox potentials is due to the strong electron withdrawing effect of eight β -chloro groups. The thermogram of VOTPPCl₈ exhibited almost a flat line till 390 °C indicating the high thermal stability of this porphyrin (Figure S6, ESI). The high stability of VOTPPCl₈ is possibly due to sterically hindered porphyrin periphery (nonplanar saddle shape conformation) and electron withdrawing β -chloro groups which prevent the oxidative decomposition.^{4a} To the best of our knowledge, this is the first example of metalloporphyrin showing very high thermal stability (till 390 °C) which prompted us to do catalytic oxidation studies using this vanadylporphyrin complex.

We have recorded the X-band EPR spectrum of VOTPPCl₈ in toluene (Figure 5). VOTPPCl₈ has exhibited axial EPR spectrum with well resolved ⁵¹V hyperfine lines at 120 K. The spin Hamiltonian parameters were obtained from simulated EPR spectrum which is in close agreement with experimentally observed one. The obtained $g_{||}$ and g_{\perp} values are 1.965 and 1.985, respectively and $A_{||}$ and A_{\perp} values are 172×10^4 cm⁻¹ and 61×10^4 cm⁻¹, respectively. The $g_{||} < g_{\perp}$ and $A_{||} \gg A_{\perp}$ relationships are normal for the axially compressed d_{xy}^1 configuration.^{24c,28} These results clearly indicate that vanadium

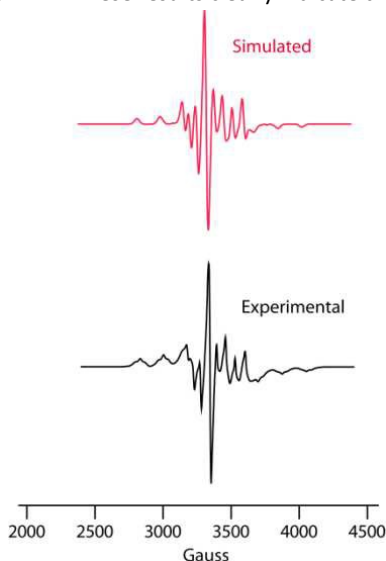

Figure 5. X-Band EPR spectrum of VOTPPCl₈ was recorded in toluene at 120 K (bottom). EPR parameters: microwave frequency, 9.453 GHz; incident microwave power, 0.189 mW; modulation frequency, 100.0 kHz; modulation amplitude, 5.0 G; receiver gain, 1×10^4 . Simulated EPR spectrum of VOTPPCl₈ is shown at the top.

is in IV oxidation state. Further, we couldn't observe well resolved superhyperfine splitting from porphyrin N atoms

since the unpaired electron resides on a σ -non-bonding orbital pointing away from these N atoms which is present in the equatorial (xy) plane.²⁸

Catalytic Studies

To explore the catalytic potential of synthesized vanadium porphyrin complex (VOTPPCl₈), we conducted a series of experiments. Catalytic oxidation of cyclohexene by VOTPPCl₈ using H₂O₂ as oxidant and NaHCO₃ as co-catalyst gave three products: cyclohexene epoxide (**1**), 2-cyclohexen-1-ol (**2**) and 2-cyclohexen-1-one (**3**).

Scheme 1 Oxidation of cyclohexene catalyzed by VOTPPCl₈.

The catalytic activity of VOTPPCl₈ was initially investigated for cyclohexene as a representative oxidation substrate and different reaction parameters were optimized for 5 mmol (0.410 g) of cyclohexene in 6 hours of reaction time. All the catalytic experiments were carried out in a 50 mL round bottom flask containing cyclohexene (0.410 g, 5 mmol), appropriate amount of aqueous 30% H₂O₂, NaHCO₃ in 5 mL of desired solvent and fitted with a condenser. At first, the effect of different types of solvents *viz.* acetonitrile, methanol, dichloromethane and toluene (5 mL each), on the oxidation of 5 mmol (0.410 g) of cyclohexene was studied using 10 mmol (1.13 g) of 30% H₂O₂ and 1 mmol (0.084 g) of NaHCO₃ as promoter at 60 °C. CH₃CN was found to be the most suitable solvent with the maximum of 61% conversion followed by 57% conversion of cyclohexene using methanol as a solvent (data not shown). The possible reason for the increased conversion is due to the enhanced formation of oxidohydroperoxido- or oxidoperoxovanadium(V) species. Therefore, CH₃CN was used as a solvent for the optimization of remaining reaction conditions.

The catalyst amount was optimized by taking three different amounts of catalyst (0.0005 g, 0.0010 g and 0.0015 g) while keeping other reaction parameters constant such as 30% H₂O₂ (1.13 g, 10 mmol), NaHCO₃ (0.084 g, 1 mmol), acetonitrile (5 mL) and reaction temperature (60 °C). The conversion increased from 61% to 73% by increasing the catalyst amount from 0.0005 g to 0.0010 g as presented in Table 1 (entry 2). Thereafter, no considerable improvement in conversion was obtained (77%) upon increasing the catalyst amount up to 0.0015 g and hence catalyst amount 0.0010 g (1.04 μ mol) was considered as optimized catalyst amount.

The effect of oxidant amount *i.e.* aq. 30% H₂O₂ was measured by varying its amount. For this purpose, three different oxidant amount *viz.* 5, 10 and 15 mmol were chosen and reactions were carried out by taking 1.04 μ mol of catalyst, 1 mmol of promoter (*i.e.* NaHCO₃) and 5 mL of CH₃CN at 60 °C. The

13	1.0, 1.04	1.13, 10	–	5	60	58	19	42	39
14	–	1.13, 10	0.168, 2	5	60	16	11	58	31
15	–	1.13, 10	–	5	60	5	9	56	35

H₂O₂ and comparable conversions were obtained while increasing H₂O₂ amount up to 10 mmol (77 %) and 15 mmol (78 %). Considering these observations, 10 mmol of 30% H₂O₂ was concluded best for the maximum oxidation of cyclohexene (entry 2, Table 1).

The amount of promoter NaHCO₃ also affects the oxidation of cyclohexene. This effect has been examined by conducting experiments with three different NaHCO₃ amounts (1, 2 and 3 mmol) while maintaining other reaction parameters (1.04 μmol of catalyst, 10 mmol of 30% H₂O₂, 5 mL of CH₃CN, temperature 60 °C) consistent. An increase in the conversion from 73% to 82% was achieved by increasing the amount of sodium bicarbonate from 1 mmol to 2 mmol. Using 3 mmol of sodium bicarbonate didn't increase the conversion significantly (85% conversion, as presented in Table 1) and therefore, 2 mmol NaHCO₃ amount was optimized for further optimization (entry 6, Table 1).

The solvent (CH₃CN) amount is also an important factor in terms of percentage conversion of cyclohexene. The effect of different amounts of solvent is shown in Table 1 under above optimized conditions i.e. catalyst (0.0010 g, 1.04 μmol), 30% H₂O₂ (1.31 g, 10 mmol), NaHCO₃ (0.168 g, 2 mmol) at 60 °C reaction temperature. While using 5 mL of acetonitrile 82% of cyclohexene

conversion was obtained which was reduced to 68% for 7 mL of CH₃CN possibly due to the dilution effect. The conversion was slightly decreased (81%) when 3 mL of solvent amount was employed. Considering all these facts, 5 mL of CH₃CN was chosen as optimal solvent amount for cyclohexene oxidation.

To understand the dependence of cyclohexene oxidation over reaction temperature, reactions have been carried out at different temperatures i.e. room temperature (30 °C), 50, 60 and 70 °C temperature under the optimized conditions for 6 hours. The oxidation of cyclohexene was found to be slowest at room temperature (30 °C) with only 35 % conversion. The catalytic activity of the catalyst VOTPPCl₈ increased significantly on increasing temperature from room temperature to 70 °C. A conversion of 51 % was obtained for 50 °C which was also further increased up to 82 % and 86 % for 60 °C and 70 °C, respectively (Table 1).

Details of all experimental conditions are presented in Table 1. Thus, the optimized reaction conditions for the oxidation of 5 mmol of cyclohexene are (entry no. 6, Table 1): catalyst [VOTPPCl₈] (0.0010 g, 1.04 μmol), 30% aqueous H₂O₂ (1.13 g, 10 mmol), CH₃CN (5 mL) and temperature 60 °C. The selectivity of different oxidation products under the optimized reaction condition is: 22% cyclohexene epoxide (1), 42% 2-cyclohexen-1-ol (2) and 36% 2-cyclohexen-1-one (3). To investigate the effect of both catalyst (VOTPPCl₈) and promoter (NaHCO₃) on the oxidation of cyclohexene, three types of controlled experiments were performed under the optimized conditions (Table 1): (i) The control experiment in the absence of catalyst (VOTPPCl₈) but with promoter NaHCO₃ under optimized conditions gave 16% of conversion (entry no. 14), (ii) The control experiment in the absence of promoter NaHCO₃ but with catalyst (VOTPPCl₈) under optimized conditions gave 58% of conversion (entry no. 13) and, (iii) The control experiment in the absence of both promoter NaHCO₃ and catalyst (VOTPPCl₈) under optimized conditions gave only 5% of conversion after 6 hours of reaction time (entry no. 15).

Table 2. Product distribution for the oxidation of cyclohexene (5 mmol) using VOTPPCl₈ as catalyst (1 μmol) and 10 mmol of 30% H₂O₂ as an oxidant under

different reaction conditions.

These control experiments demonstrate that the catalyst itself is moderately efficient in catalytic oxidation of cyclohexene using 30% H₂O₂ as an oxidant with adequate conversion of 58% even in the absence of any promoter. But the product selectivity for cyclohexene epoxide decreased from 22% to 13% (Table 2, entry no. 2), whereas, only 5% of cyclohexene was converted in the absence of both catalyst and promoter showing their catalytic roles in the oxidation (entry 15, Table 1). However, 16% of cyclohexene conversion was observed using NaHCO₃ alone in the reaction. Surely the use of NaHCO₃ as promoter activated the oxidant H₂O₂ and resulted in the increased catalytic efficiency of the catalyst (VOTPPCl₈) towards oxidation of cyclohexene in respect of both the conversion and selectivity of epoxide.^{18-19,21-22}

Such type of activation of H₂O₂ with bicarbonate ion has been demonstrated by Drago and co-workers²⁹ and Richardson *et al.*³⁰ in sulfide oxidations using a solvent mixture of alcohol/water. Richardson *et al.*²² have reported that HCO₃⁻, which is an essential component in such systems, forms a peroxymonocarbonate ion, HCO₄⁻ and exists as following equilibria and is more active (more nucleophilicity) oxidant than H₂O₂.

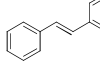

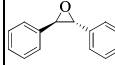

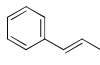

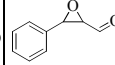

Later, this bicarbonate-activated peroxide (BAP) system, was adopted for olefin epoxidation using H₂O₂ as terminal oxidant in CH₃CN solvent^{18,19} and in water/co-solvent mixture.²² All these facts and our previous results showing respectable amount of selectivity towards epoxide (i.e. 22 %, Table 2, entry no. 1) under the optimized conditions led us to investigate that how the solvent mixture of water with CH₃CN or CH₃OH (as we have stated previously that comparable results were obtained with methanol) affects the cyclohexene conversion and epoxide selectivity?

To understand the effect of these solvent mixtures, the experiments were conducted under above stated optimized condition. The use of CH₃CN/H₂O (3 mL/2 mL, v/v) at 60 °C mixture dramatically improved the catalytic efficiency of the catalyst (VOTPPCl₈) and almost all cyclohexene was converted into epoxide (99% selectivity) within half an hour of reaction time (Table 2, entry no. 3). Using CH₃CN/H₂O (3mL/2mL, v/v) mixture at room temperature yielded 51% of conversion in 2 hours of reaction time with reduced 30% selectivity for cyclohexene epoxide (**1**) and increased 44% and 26% selectivity for the allylic oxidation products 2-cyclohexen-1-ol (**2**) and 2-cyclohexen-1-one (**3**), respectively. Similarly, in methanol/water (3 mL/2 mL, v/v) mixture 97% conversion was obtained in 0.5 hour time scale at 60 °C but with poor cyclohexene epoxide (**1**) selectivity i.e. 7% (Table 2, entry no.7) and a maximum of 45% conversion was obtained at room temperature with 18% selectivity towards epoxide. The similar trend of epoxide selectivity for acetonitrile and methanol was observed throughout the series of experiments (i.e. the epoxide selectivity is always higher if CH₃CN is used as solvent alone or with water).

Finally, an optimized condition both in the respect of percentage conversion and epoxide selectivity was achieved for the cyclohexene oxidation as follows: catalyst (VOTPPCl₈) (0.0010 g, 1.04 μmol), 30% aqueous H₂O₂ (1.13 g, 10 mmol), CH₃CN/H₂O (3 mL/2 mL, v/v) and temperature 60 °C. Under this optimised condition, we have carried out the epoxidation reactions of various olefins and the results are summarized in Table 3.

Table 3. Oxidation of different olefins using 1.04 μmol of VOTPPCl₈ as catalyst, 30% H₂O₂ as terminal oxidant and sodium bicarbonate as promoter using CH₃CN/H₂O solvent mixture under the optimized reaction conditions.

Catalytic Mechanism

Scheme 1 Plausible catalytic mechanism for the conversion olefins to epoxides using VOTPPCl₈ catalyst.

We tried UV-Visible spectral titration of VOTPPCl₈ in presence of H₂O₂/NaHCO₃ in CH₃CN/H₂O mixture and found no spectral changes are observed. So, we have carried out ⁵¹V NMR experiments in order to ascertain the intermediate formed during the catalytic reaction. H₂O₂ and HCO₃⁻ are used together to increase the activity of H₂O₂ by the *in situ* generation of HCO₄⁻ which is more nucleophilic than H₂O₂ and thus attributes to the enhanced oxidizing activity of the metal complexes and to speed up the reaction.¹⁸⁻²² Hence, in the presence of H₂O₂ and NaHCO₃, the solution of VOTPPCl₈ in DMSO-d₆ is converted into oxidoperoxidovanadium(V), [VO(O₂)TPPCL₈]⁻ with a resonance at -618.4 ppm and remains stable for two days as shown in the Figure 6. The addition of cyclohexene decreases the peak intensity at -618.4 ppm by heating to 50 °C for 5 minutes (Figure 6c). Further, the peak at -618.4 ppm is completely diminished by adding excess of cyclohexene and heating at 50 °C for 10 minutes (Figure 6d). The peak appeared at -618.4 ppm in ⁵¹V NMR indicates the formation of oxidoperoxidovanadium(V) species.^{18,19,31-35} In general, oxidoperoxidovanadium(V) species,^{18,19,31,33-35} [VO(O₂)TPPCL₈]⁻ is more stable as compared to oxidohydroperoxidovanadium(V), [VO(O-OH)TPPCL₈] species^{32,33} in which hydroperoxide ion binds in side-on mode.^{18,19,31-35} Hence, the 100% selectivity for epoxide formation in good yields (70-100%) from olefin to epoxide by VOTPPCl₈ catalyst is possibly due to the formation of oxidoperoxidovanadium(V) intermediate, [VO(O₂)TPPCL₈]⁻ which converts olefin to epoxide selectively.^{18,19} Further, we have carried out MALDI-TOF mass analysis to identify the catalytic intermediate. VOTPPCl₈ (0.02 mol%) was heated in presence of H₂O₂ (2 equiv.) and NaHCO₃ (0.4 equiv) in CH₃CN at 60 °C for 30 minutes. Then the reaction mixture was cooled to RT and subjected to MALDI-TOF mass analysis using HABA matrix. The peak at m/z 989.3 clearly indicates the formation of oxidoperoxidovanadium(V) species (Figure S7 in the ESI). Cyclohexene (0.410 g, 5 mmol) was added to the reaction

Figure 6. ⁵¹V NMR spectra of VOTPPCl₈ (5.2 μmol) in DMSO-d₆ in the presence of: (a) 0.36 mmol of 30% aq. H₂O₂ and 0.3 mmol of NaHCO₃, 10 mins after addition, a peak appeared at -618.4 ppm; (b) after 48 hours; (c) 1.2 mmol of cyclohexene was added and heated for 5 mins at 50 °C; (d) large excess of cyclohexene was added and heated for 10 minutes at 50 °C.

mixture containing oxidoperoxidovanadium(V) species and heated to 60 °C for 30 minutes. In MALDI-TOF mass analysis, the disappearance of peak at m/z 989.3 indicates the consumption of oxidoperoxidovanadium(V) species (Figure S8 in the ESI). This experiment further proves the existence of oxidoperoxidovanadium(V) species as reaction intermediate in addition to ⁵¹V NMR studies.

The reason for very high TOF numbers (6566-9650 h⁻¹) is due to high thermal and chemical stability of VOTPPCl₈ which resist for thermal as well as chemical oxidative degradation and further bulkiness prevents the bimolecular attack. At the end, the obtained epoxide product was distilled off and catalyst was recovered. The isolated yields are approaching close to GC yields. For example, the isolated yields of 1-octene epoxide, *trans*-stilbene epoxide and *cis*-cyclooctene epoxide were found to be 94%, 84% and 93%, respectively. The UV-Vis absorption spectral features of VOTPPCl₈ didn't change before and after catalytic reaction indicating its high thermal and chemical stability as shown in Figure S9 in the ESI.

Conclusions

We have synthesized VOTPPCl₈ in good yield and characterized by various spectroscopic techniques. DFT optimized structure of VOTPPCl₈ in CH₃CN exhibited severe nonplanar saddle shape conformation and the oxidation state of metal ion (V^{IV}) was confirmed by EPR spectroscopy. CV studies revealed the electron deficient nature of porphyrin π-system by showing remarkable anodic shift in redox potentials as compared to VOTPP. VOTPPCl₈ showed very high thermal stability till 390 °C due to electron deficient nonplanar porphyrin core. Further, VOTPPCl₈ was utilized for the selective epoxidation of various olefins in good yields in presence of H₂O₂/NaHCO₃ in CH₃CN/H₂O mixture. The formation of oxidoperoxidovanadium(V) intermediate during catalytic cycle was probed by ⁵¹V NMR studies and MALDI-TOF mass analysis. This porphyrin catalyst (VOTPPCl₈) has higher thermochemical stability and recyclability. However, anchoring of these catalysts in polymers or mesoporous materials (heterogenization) in high concentrations would be important for the commercial applications. Currently, we are working on the said topic and the results will be reported in the near future.

Experimental Section

Chemicals and materials

CH₃CN and DMF employed in the present work were of analytical grade and distilled before use. VOSO₄ and NaHCO₃ were obtained from HiMedia, India and used as received. Various alkenes used in this study were purchased from Alfa Aesar and used as received. Silica gel (100 - 200 mesh) used for column chromatography was purchased from Rankem, India and used as received. TBAPF₆ was obtained from Alfa Aesar, India and recrystallized twice from ethanol followed by drying under vacuum at 60 °C for 10 h.

Instrumentation and methods

UV-Vis absorption spectra were measured in distilled CH_2Cl_2 using Agilent Cary 100 spectrophotometer. IR spectra were recorded in the mid IR range of $4000\text{--}400\text{ cm}^{-1}$ on a Perkin-Elmer spectrophotometer by making KBr pellets. Elemental analysis was carried out using Elementar Vario EL II instrument. ^{51}V NMR spectra were recorded on JEOL ECX 400 MHz spectrometer using DMSO-d_6 as a solvent containing 0.03% TMS (v/v). MALDI-TOF-MS spectra were measured using a Bruker UltrafleXtreme-TN MALDI-TOF/TOF spectrometer using HABA as a matrix. Cyclic voltammetric measurements were carried out using CHI 620E instrument in triple distilled CH_2Cl_2 containing 0.1 M TBAPF₆ as supporting electrolyte under argon atmosphere. A three electrode assembly was used consisting of a Pt disk working electrode, Ag/AgCl as a reference electrode and a Pt-wire as a counter electrode. Electron paramagnetic resonance spectra were obtained on a Bruker EMX EPR spectrometer in toluene solvent at 120 K. The spin Hamiltonian parameters were obtained from simulated EPR spectrum. Thermal analyses were performed with SII EXSTAR 6300 instrument. DFT studies were carried out using B3LYP functional with LANL2Z basis set. The oxidation products were quantified using a Shimadzu 2010 plus gas-chromatograph equipped with an Rtx-1 capillary column ($30\text{ m} \times 0.25\text{ mm} \times 0.25\text{ }\mu\text{m}$) and an FID detector. GC-MS analyses were carried out using Perkin-Elmer GC-MS (Clarus 500).

Synthesis of 2,3,7,8,12,13,17,18-octachloro-meso-tetraphenylporphyrinato vanadium(IV) (VOTPPCl₈):

H_2TTPCl_8 (0.18 g, 0.202 mmol) was dissolved in 40 mL of DMF. To this, 10 equiv. of VOSO_4 (0.518 g, 2.02 mmol) was added and refluxed for 16 hours under argon atmosphere. At the end of this period the reaction mixture was cooled to room temperature and then 120 mL of distilled water was added. Porphyrin was precipitated out and filtered through G-4 crucible. The crude product was purified on silica column using CHCl_3 as eluent. Yield was found to be 0.152 g (0.16 mmol, 79%).

UV-Vis (CH_2Cl_2): λ_{max} (nm) ($\log\epsilon$) 354 (4.01), 452 (5.15), 578 (4.00), 618 (sh); IR (KBr, cm^{-1}) 1003 ($\nu_{\text{V=O}}$); MALDI-TOF-MS (m/z): found 954.95 [M]⁺, calcd. 954.96; elemental analysis calcd. for $\text{C}_{44}\text{H}_{20}\text{N}_4\text{Cl}_8\text{VO}$: C, 55.32%; H, 2.11%; N, 5.87% and found: C, 55.23%; H, 2.28%; N, 5.98%.

Catalytic activity studies

The catalytic efficiency of VOTPPCl₈ was tested for the oxidation of various alkenes. In a typical catalytic experiment, 5 mmol (0.410 g) cyclohexene, 10 mmol 30 % H_2O_2 (1.13 g), 1 mmol NaHCO_3 (0.084 g) and 5.23×10^{-4} M (0.0005 g) of VOTPPCl₈ were added into a 5 mL of CH_3CN in a round bottom flask fitted with a condenser. The flask was placed in an oil bath and the temperature was kept 60 °C throughout the reaction time with 500 RPM mechanical stirring. After the

reaction was finished, reaction mixture was filtered and its 1 mL portion was subjected to multiple heptane extraction. The extract was concentrated and its 0.2 μL was injected to the GC/GC-MS. The oxidation products were quantified using a Shimadzu 2010 plus gas-chromatograph equipped with an Rtx-1 capillary column ($30\text{ m} \times 0.25\text{ mm} \times 0.25\text{ }\mu\text{m}$) and an FID detector. The product identities were confirmed by a Perkin-Elmer GC-MS (Clarus 500).

Acknowledgements

MRM thanks Department of Science and Technology (DST) and Council of Scientific and Industrial Research (CSIR), India for the financial support. MS sincerely thanks Science and Engineering Research Board (SB/FT/CS-015/2012), Council of Scientific and Industrial Research (01(2694)/12/EMR-II) and Board of Research in Nuclear Science (2012/37C/61/BRNS/2776) for funding. RK thanks Ministry of Human Resource development (MHRD), Govt. of India for fellowship and NC sincerely thanks CSIR for senior research fellowship. We sincerely thank department of biotechnology, IIT Roorkee for carrying out MALDI-TOF mass analysis.
