The syntheses of two previously known, 2-((2-aminoethyl)(pyridin-2-ylmethyl)amino)ethanol (1) and 2-((3-aminopropyl)(pyridin-2-ylmethyl)amino)ethanol (2) and four new unsymmetrical N-capped tripodal

- ¹⁰ amines, 2-((4-aminobutyl)(pyridin-2-ylmethyl)amino)ethanol (**3**), 3-((2-aminoethyl)(pyridin-2ylmethyl)amino)propan-1-ol (**4**), 3-((3-aminopropyl)(pyridin-2-ylmethyl)amino)propan-1-ol (**5**) and 3-((4-aminobutyl)(pyridin-2-ylmethyl)amino)propan-1-ol (**6**) are reported. The ligands (**3**)-(**4**) feature a longer arm, 3-hydroxypropyl or butylamino, than in the analogues previously employed (2-hydroxyethyl arm, ethylamino-arm or propylamino-arm in **1** and **2**). All six tripodal amines, **1-6**, are equipped with a 2-
- ¹⁵ methylpyridyl-arm and either an ethylamino-arm (1 and 4), propylamino-arm (2 and 5) or butylaminoarm (3 and 6). The new amines, 3-6, have been employed in one pot condensation reactions with 2hydroxy-1-naphthaldehyde and salicylaldehyde (and its derivatives) in the presence of Cu(II) metal ion to generate a series of new mononuclear complexes, $[M^{II}L^{aldi}](CIO_4)$ as well as new dinuclear complexes $[Cu^{II}L^{aldi}]_2(CIO_4)_2$ of new ligands L^{aldi} . Four monomeric complexes and one dimeric complex have been
- ²⁰ characterised by single crystal X-ray diffraction, revealing a distorted square-pyramidal copper(II) ion. A general comparison between these structures show that the number and the type of chelate rings sequence around the metal ions are important in the formation of structures. Theoretical studies show that the 3-hydroxypropyl arm in these complexes is a weak coordinating group and it can readily be removed from the coordination sphere of metal ion, resulting in a dimerised four coordinate complex. Calculations show

25 that the interaction between the two monomeric fragments is very weak.

Introduction

Recently, research on tripodal ligands and their related complexes has been an expanding field and is the subject of numerous reports.¹ Transition metal complexes synthesised with this type of ³⁰ ligand display special physical, chemical or structural properties,

- such as unusual conformation, high thermodynamic stability and virtual kinetic inertness.² These tripodal ligands can also serve as precursors to the synthesis of interesting macrobicyclic compounds^{3,4} which usually require high dilution techniques⁵ or ³⁵ the use of metal ions as templates.^{6,7} The synthesis of model
- complexes mimicking the spectroscopic and structural properties of metalloproteins active sites can be undertaken by employing multidentate tripodal ligands, most of which possess aromatic donor functions like pyridyl and/or phenolic groups.⁸ However,
- ⁴⁰ the chemistry of asymmetric N-capped tripodal ligands which possess three pendant arms with different donor groups has not been well explored.^{9,10} This type of tripodal ligand is of particular

interest in the context of modeling the asymmetric active metal sites such as those found in nitrile hydratase,11 and horse liver 45 alcohol dehydrogenase.¹² Among these asymmetric N-capped tripodal ligands, our group is particularly interested in unsymmetric N-capped tripodal ligands with two different aliphatic arm lengths and one aromatic pendant arm. However these tripodal ligands bearing one pyridine arm are scarce.¹³ As 50 part of a program to explore the coordination chemistry of partially unsymmetric tripodal N₃O₂ ligands, we herein report the synthesis and characterisation of new Cu complexes and compare them with our previous work. A direct influence of the lengths of the alkyl chains between central and terminal donor function on 55 the complex geometry was observed for the cadmium(II), nickel(II) and copper(II) complexes of these unsymmetrical tripodal ligands featuring different spacer lengths (Fig. 1). The coordination behavior towards Cd(II), Ni(II) and Cu(II) was investigated for ligands Laldi combining pyridine, amine, and 60 alkoxy donor functions on ethylene, propylene and butylene spacers.14

This journal is © The Royal Society of Chemistry [year]

In previous work, we reported the synthesis of two new unsymmetical triamines, (1) and (2), both of which feature three different arms: 2-methylpyridyl, either ethylamino- or propylamino, and ethanol (Figure 1).¹⁴ Reaction of (1) or (2) with s salicylaldehyde and its analogues gave a wide selection of

- compounds with which to probe the effects of strain in the resulting cadmium(II) and nickel(II) Schiff base complexes (Figure 1).¹⁴ When the shorter ethylene linker was used between the tertiary and primary amine nitrogen atoms, a mononuclear
- ¹⁰ Schiff base complex was structurally characterised in the case of $[Ni^{II}L^{OMe1}]^+$ whereas the more flexible propylene linker $(L^{OMe2})_2^{2+}$ and L^{H2} ligands) gave dinuclear complexes, $[Ni^{II}L^{OMe2}]_2^{2+}$ and $[Cd^{II}L^{H2}]_2^{2+}$, which were structurally characterised. The nickel(II) centre in $[Ni^{II}L^{OMe1}]^+$ has a distorted square planar geometry, ¹⁵ whereas in $[Ni^{II}L^{OMe2}]_2^{2+}$ the geometry is distorted octahedral, as with the cadmium(II) ion in $[Cd^{II}L^{H2}]_2^{2+,1}$. The structural types

observed to date are summarised in Figure 1. In this paper the effect of employing a 3-hydroxypropyl arm in place of the 2-hydroxyethyl arm, and a butylamino arm in place 20 of the ethylamino or propylamino arm, on the outcome of one pot condensations with various salicylaldehydes in the presence of copper(II) ion has been studied. Hence the synthesis of four new unsymmetrical tripodal triamines, 2-((4-aminobutyl)(pyridin-2vlmethyl)amino)ethanol(3), 3-((2-aminoethyl)(pyridin-2-25 ylmethyl)amino)propan-1-ol (4), 3-((3-aminopropyl)(pyridin-2ylmethyl)amino)propan-1-ol (5) or 3-((4-aminobutyl)(pyridin-2ylmethyl)amino)propan-1-ol(6), is reported (Figure 1). The synthesis and physical properties of the new Cu(II) complexes of the new ligands, HL^{H3-6}, HL^{OMe3-6} and HL^{tBu3-6} formed in situ 30 from the condensation of 2-hydroxybenzaldehyde with 3-6 (HL^{H3-6}), 2-hydroxy-3-methoxy-benzaldehyde with 3-6 (HL^{OMe3-} 6), 3,5-di-tert-butylsalicylaldehyde with 3-6 (HLtBu3-6) and, for the first time, with 2-hydroxy-1-naphthaldehyde with 1-6 (HL^{napht1-6}), are reported here. In addition, the X-ray crystal $[Cu^{II}L^{napht2}](ClO_4),$ $[Cu^{II}L^{OMe3}](ClO_4),$ 35 structures of $[Cu^{II}L^{H3}](ClO_4)$, $[Cu^{II}L^{H4}](ClO_4)$ and dimeric $[Cu^{II}L^{H5}]_2(ClO_4)_2$, are described.

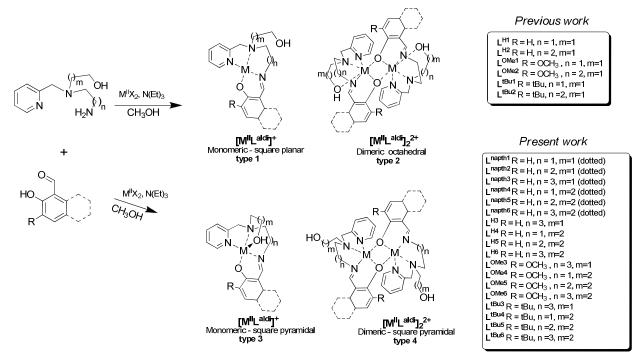

Figure 1. Summary of the range of structural motifs identified to date for complexes resulting from the condensation of a range of salicylaldehydes with the unsymmetrical triamines 1 (n = 1, m=1) and 2 (n = 2, m = 1) with 2-hydroxyethyl arms but differing amino-arm lengths. The present study concerns complexes of the new ligands highlighted in the box, HL^{H3-6}, HL^{DMe3-6}, HL^{EBU3-6} and HL^{napht1-6} (X = ClO₄⁻).

Results and discussion

Four new unsymmetrical tripodal amines, 2-((4aminobutyl)(pyridin-2-ylmethyl)amino)ethanol (3), 3-((2-45 aminoethyl)(pyridin-2-ylmethyl)amino)propan-1-ol (4), 3-((3aminopropyl)(pyridin-2-ylmethyl)amino)propan-1-ol (5) and 3-

((4-aminobutyl)(pyridin-2-ylmethyl)amino)propan-1-ol (6), were prepared in high yields. Amines 3 - 6 differ from the previously used amines, 1 and 2, in that 4 and 5 feature a 3-hydroxypropyl ⁵⁰ arm in place of the 2-hydroxyethyl arm, 3 features a butylamino arm in place of the ethylamino/propylamino arm and 6 features a 3-hydroxypropyl arm in place of the 2-hydroxyethyl arm and also

a butylamino arm in place of the ethylamino/propylamino arm

(Fig. S1–S12, ESI[†]). Subsequently, one pot reactions of amines 1
⁵⁵ - 6 with 2-hydroxy-1-naphthaldehyde and salicylaldehyde derivatives in the presence of a Cu(II) metal salt were employed to generate new Cu(II) complexes of Schiff-base ligands L^{aldi}, where ^{aldi} is H3-6, OMe3-6, tBu3-6 and napht1-6 (Figure 1). Recrystallisation of powders obtained from the reaction mixture ⁶⁰ by vapour diffusion of diethyl ether (see experimental section below) gave either purified powders or single crystals which were analysed by single crystal X-ray diffraction, showing four monomeric and one dimeric compounds (*vide infra*).

The infrared spectra of all complexes (Fig. S13–S30, ESI[†]) show $_{65}$ a band at ca. 1613–1632 cm⁻¹, attributable to the imine groups, and no bands due to v(C=O) vibrations. Medium to strong bands

at ca. 1596–1612 and 1437–1462 cm⁻¹ are present in all cases, and correspond to the two highest energy ring vibrations of the coordinated pyridine.^{14,15} Absorptions attributable to the perchlorate ions are seen at approximately 1051–1088 and 619– ⁵ 625 cm⁻¹. The lack of splitting suggests that they are not coordinated.

The positive ion electrospray mass spectra of all complexes (Fig. S31–S48, ESI†) show a common peak, which is the fragment $[Cu^{II}L^{aldi}]^+$ associated with the loss of the ClO₄⁻ anion. The four

- ¹⁰ copper(II) complexes using $(\mathbf{L}^{ald5})^{-}$ as a ligand appear to be dimeric complexes $[Cu^{II}\mathbf{L}^{ald5}]_2(ClO_4)_2$ as the mass spectra exhibit peaks of very weak intensity consistent with the presence of a dication $[Cu\mathbf{L}^{ald5}]_2^{2^+}$. In all copper(II) complexes the most intense peaks are for the mononuclear $[Cu^{II}\mathbf{L}^{aldi}]^+$ species which indicates
- ¹⁵ that the dimer is unsurprisingly broken apart. On the other hand, a peak with a very weak intensity corresponds to $[ML^{aldi}]_2^+$ fragment is observed in most of the mononuclear complexes in present work and also in our previous work,¹⁴ even when their Xray crystal structures show that they are mononuclear complexes.
- ²⁰ Thus it seems that the [ML^{aldi}]₂⁺ fragment observed in the mass spectra of the mononuclear complexes is formed due to a very small dimerization occurring in the mass spectrometer.

UV-Vis spectra of the fourtheen Cu(II) complexes in CH₃CN solution showed a broad low-intensity absorption band occurring

- $_{25}$ in the range 574 nm $<\lambda_{max}<630$ nm with molar extinction coefficient ranging between 92 $M^{-1}~cm^{-1}<\epsilon<174~M^{-1}~cm^{-1}$. This is assigned to a d–d transition and is characteristic of five-coordinate copper(II) complexes with square pyramidal or distorted square pyramidal geometries, which generally exhibit a
- ³⁰ band in the 550-660 nm range (dxz, dyz \rightarrow dx²-y²).¹⁶⁻²⁴ In the case of four Cu complexes [Cu^{II}L^{aldi}]ClO₄ (i=3), the respective λ_{max} values in the range 600 nm $< \lambda_{max} < 633$ nm and 121 M⁻¹ cm⁻¹ $< \epsilon < 157$ M⁻¹ cm⁻¹ (each with a shoulder at 761-819 nm) are also indicative of square-pyramidal coordination according to the
- ³⁵ literature.^{25,26} In addition, a few absorption bands are found in the range 205–406 nm for all Cu(II) complexes, due to either charge transfer or π - π * transitions.^{19, 21, 27-29} Although the UV-Vis spectra of complexes with polydentate Schiff base ligands are not generally good indicators of geometry, the evidence gathered ⁴⁰ helps to support this geometry.
- Room temperature magnetic moments were obtained for all mononuclear Cu(II) complexes. The magnetic moment values for these complexes lie in the 1.82–1.95 B.M. range. These values are close to the expected spin only magnetic moment value (1.73
- ⁴⁵ BM) for d⁹ Cu(II) system³⁰ with single unpaired electron. For the four dinuclear copper complexes, the observed values of magnetic moment lie in the 1.32–1.66 BM range per Cu atom.

Crystal structures of $[Cu^{II}L^{napht2}](CIO_4)$, $[Cu^{II}L^{H3}](CIO_4)$, $[Cu^{II}L^{OMe3}](CIO_4)$ and $[Cu^{II}L^{H4}](CIO_4)$

- ⁵⁰ Green single crystals of [Cu^{II}L^{napht2}](ClO₄), [Cu^{II}L^{H3}](ClO₄), [Cu^{II}L^{OMe3}](ClO₄) and [Cu^{II}L^{H4}](ClO₄) suitable to be studied by X-ray diffraction were obtained by slow diffusion of diethyl ether into a solution of the complex in MeOH. Crystal data and structure refinement are given in Table 1. These complexes are
- ⁵⁵ monometallic but differ in the space group adopted (P2₁/c, C2/c, P-1 and I2/a respectively). The molecular structures, as well as selected bond lengths and angles are given in Figure 2 and Table 2, respectively, and a comparison with the literature is also

shown. The X-ray crystal structures of these complexes consist of $_{60}$ [Cu^{II}L^{napht2}]⁺, [Cu^{II}L^{H3}]⁺, [Cu^{II}L^{OMe3}]⁺ and [Cu^{II}L^{H4}]⁺ cations and perchlorate anion. The Cu(II) ion display a distorted square pyramidal coordination, involving three N atoms and two O atoms. In comparison to the mononuclear [Ni^{II}L^{OMe1}](ClO₄) complex reported in our previous work,¹⁴ in which the hydroxyl 65 group is not coordinated, in these mononuclear copper(II) complexes it is coordinated to the apical site of the approximate square pyramidal copper(II) ion (Table 2). As expected, this axially bound O donor atom makes a bond that is slightly longer than bond distances in basal plane (~2 Å). Among the Cu-N 70 bonds, those involving the tertiary amine nitrogen atoms are the longest in all Cu complexes. The second longest Cu-N bond formed in both mononuclear and dinuclear complexes involves the Cu-N_{py} bonds. Comparison of the same bond lengths of square pyramidal Cu(II) complexes reported here with related 75 reports in the literature are summarised in Table 2.14, 19, 31-38 The X-ray crystal structure analysis shows that in the case of $[Cu^{II}L^{OMe3}](ClO_4)$, two $[Cu^{II}L^{OMe3}]^+$ cations are bonded through hydrogen bonding. Indeed, the hydrogen atom of the hydroxyl group of one cation is engaged in hydrogen bonding with the ⁸⁰ phenolic oxygen atom of the adjacent cation and vice versa (Fig. 5a). It seems that these intermolecular interactions between two molecules of such five coordinate complex in $[Cu^{II}L^{OMe3}](ClO_4)$ are relatively strong and prevent the formation of dinuclear compounds (see section theoretical studies). Note that the dataset 85 for [Cu^{II}L^{OMe3}](ClO₄) was particularly bad, leading to a high R1 factor, this despite our best efforts to grow better crystals - the results presented here are from the best dataset obtained.

Variation of the length of the ligand arms leads to different size of chelate rings. These tripodal ligands are capable of forming 90 both five and six membered chelate rings incorporating the copper ion in $[Cu^{II}L^{napht2}](CIO_4)$, $[Cu^{II}L^{H4}](CIO_4)$ and $[Cu^{II}L^{H5}]_{2}(ClO_{4})_{2}$ and also five, six and seven membered chelate rings in [Cu^{II}L^{H3}](ClO₄) and [Cu^{II}L^{OMe3}](ClO₄). For all complexes, the Namine-Cu-Npy angles are smaller than 90° [80.5-95 84.3°] for five membered chelate rings. The larger six-membered chelate rings lead to Ophenolic-Cu-Nimine angles that are all larger than 90° [90.2-94.5°]. A similar relationship between the N_{amine}-Cu-Ohydroxyalkyl and also Namine-Cu-Nimine angles and the different chelate ring sizes is described. In the case of [Cu^{II}L^{napht2}](ClO₄), ¹⁰⁰ [Cu^{II}L^{H3}](ClO₄) and [Cu^{II}L^{OMe3}](ClO₄) complexes, involving the 2-hydroxyethyl arm, the Namine-Cu-Ohydroxyalkyl angles are smaller than 90° [78.6-80.9°] for five membered chelate rings, whilst in [Cu^{II}L^{H4}](ClO₄) complex involving the 3-hydroxypropyl arm, the N_{amine} -Cu-O_{hydroxyalkyl} angle is ~ 90° [89.27°] for the six-membered ¹⁰⁵ ring. The N_{amine}-Cu-N_{imine} angle in [Cu^{II}L^{H4}](ClO₄), involving the ethylamine chain [86.37°] is smaller than 90° for five membered chelate ring, in [Cu^{II}L^{napht2}](ClO₄) and [Cu^{II}L^{H5}]₂(ClO₄)₂ complexes, involving the propylamine chain [94.2-96.2°] and also in [Cu^{II}L^{H3}](ClO₄) and [Cu^{II}L^{OMe3}](ClO₄) complexes, involving 110 the butylamine chain [102.9-104.0°] are larger than 90° for six and seven membered chelate rings, respectively (Table 2). The square pyramid in Cu complexes is somewhat trigonally distorted, as shown by the degree of trigonality, $(\tau)^{39-41}$ for Cu(1) being 0.10, 0.11, 0.066 and 0.39 for $[Cu^{II}L^{napht2}](CIO_4)$, 115 $[Cu^{II}L^{H3}](ClO_4)$, $[Cu^{II}L^{OMe3}](ClO_4)$ and $[Cu^{II}L^{H4}](ClO_4)$, respectively.

Crystal structure of [Cu^{II}L^{H5}]₂(ClO₄)₂

Green single crystals of $[Cu^{II}L^{H5}]_2(ClO_4)_2$ were obtained by slow diffusion of diethyl ether into a solution of the complex dissolved in a mixture of CH₃CN and CH₃OH, and crystallises in the ¹⁰ orthorhombic crystal system and Pbca space group. The molecular structure and selected bond lengths and bond angles relating to the coordination environment of the metal and also bond lengths related to similar compounds are given in Figure 3 and Table 2 respectively. The structure is a dinuclear, comprising ¹⁵ two similar Cu(II) centers. Each copper atom has a pentacoordinate square-pyramidal geometry. N(1), N(2), N(3) and O(2) of a deprotonated Schiff base bind four coordination sites of Cu(1). Similarly, Cu(2) is coordinated by N(1), N(2), N(3) and O(2) of another deprotonated Schiff base. The fifth, ²⁰ apical, coordination site of each Cu(1) is occupied by O(2) from another ligand, thereby forming a di-phenoxido-bridged dimer, while the hydroxypropyl arm (O(1)) of the ligand remains uncoordinated (Figure 3). The charge distribution was assigned based on the presence of only two ClO₄⁻ anions which make the ²⁵ complex a dication with two deprotonated ligands L^{H5}. Each phenoxy oxygen atom is bridging two complexes in an antisymmetric fashion giving Cu–O_{phenoxy} bond lengths of 2.407 and 1.937 Å - which is in the range of previously reported structures for copper(II) dimeric complex having phenoxy ³⁰ bridge.³⁶⁻³⁸ The coordination geometry around the copper centers is best described by the use of the τ -criterion,³⁷ indicating that the coordination geometry in [Cu^{II}L^{H5}]₂⁺ is only slightly from square-

50

pyramidal distorted ($\tau = 0.11$). In this compound, N(1), N(2), N(3) and O(2) related to the same ligand occupy the equatorial positions and O(2)', from the second ligand, occupies the apical position. The τ value for both Cu(1) in [Cu^{II}L^{H5}]₂(ClO₄)₂ is 0.11, s which is similar to the value of Cu(II) in the monomers. Thus the

geometries of both the copper centers in $[Cu^{II}L^{H5}]_2(ClO_4)_2$ are distorted square pyramidal. A 5,6,6-chelate ring sequence is observed in the dimer $[Cu^{II}L^{H5}]_2^+$, with the expected square-pyramidal coordination geometry for both Cu(II).

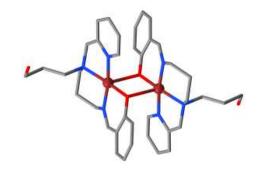

Figure 3. Perspective view of $[Cu^{IL}L^{HS}]_2(CIO_4)_2$. Hydrogen atoms and anions are omitted for clarity. Cu, C, N and O are represented in dark red, gray, blue and red, respectively.

In contrast with the coordinated ligand L^{napht2}, L^{H3}, L^{OMe3} and 15 $\mathbf{L}^{\mathbf{H4}}$ in [Cu^{II}L^{napht2}](ClO₄), [Cu^{II}L^{H3}](ClO₄), [Cu^{II}L^{OMe3}](ClO₄) and $[Cu^{II}L^{H4}](ClO_4)$ complexes, respectively, the ligand anion in complex $[Cu^{II}L^{H5}]_2^+$ uses only four of the five donor groups binding to the copper atom, in which the hydroxypropyl arm remains uncoordinated and the phenolic oxygen atom bridges two 20 Cu(II) atoms resulting in a Cu₂O₂ ring. This is not exclusively due to the steric situation in $[{\rm Cu^{II}L^{H5}}]_2({\rm ClO_4})_2,$ but to the low stability of the six-membered chelate ring which would have been formed with the hydroxypropyl ligand arm: a similar behavior of related aliphatic tripodal ligands¹⁰ and also asymmetric tripodal 25 ligand with two aliphatic and one aromatic arms has been already reported.²⁶ In addition, the stability of the copper complex with the ligand trpn, which exclusively forms six-membered chelate rings, is shown to be about 10⁵ times lower than the stability of the corresponding tren complex that contains only five-30 membered chelate rings.^{9c} Examination of the Cu(II) complexes in the present study and the literature shows that Cu(II) atom in tripodal complexes have a great flexibility in adoption of the number of the chelate rings sequence around the metal atom to form a square pyramidal geometry around the central ion as ³⁵ observed for ([Cu^{II}L^{napht2}](ClO₄), 5,5,6,6, $\tau = 0.10$; [Cu^{II}L^{H3}] (ClO₄), 5,5,7,6, $\tau = 0.11$; [Cu^{II}L^{OMe3}](ClO₄), 5,5,7,6, $\tau = 0.066$; $[Cu^{II}L^{H4}](ClO_4)$, 5,6,5,6, $\tau = 0.39$) and $([Cu^{II}L^{H5}]_2(ClO_4)_2$, 5,6,6, $\tau = 0.11$), but it should be noted that Cu(II) in these types of complexes are not stable against the high number of six-40 membered chelate rings around the metal.9c For the dinuclear complex $[Cu^{II}L^{H5}]_2(ClO_4)_2$ the hypothetical mononuclear [Cu^{II}L^{H5}](ClO₄) would possess a 5,6,6,6 chelate ring sequence around the Cu(II) atom which, due to the high number of sixmononuclear complex would prefer to form a dinuclear structure with a 5,6,6 chelate ring sequence with a second identical ligand. Table 3 show the comparison of the structural parameter (τ -value) for Cu(II) complexes characterized here.

Theoretical studies

As described above, the present study brought us three interesting results. Firstly, the formation of mononuclear five-coordinate complexes, with a majority of ligands, and dinuclear complexes, 55 with the remaining ligands. Secondly, X-ray crystal structures showed that hydrogen bonding can exist between two mononuclear five-coordinate complexes. Thirdly, mass spectra of both mononuclear and dinuclear complexes always show two characteristic peaks, one corresponding to a mononuclear 60 fragment and one corresponding to a dinuclear fragment. In order to understand these results theoretical calculations were undertaken. The strength of interaction between two mononuclear four-coordinated fragments in one dinuclear complex and hydrogen bonding between two mononuclear five-coordinated 65 complexes were evaluated (see Figure 4). From this study it is clear that one of the coordinated arms in the mononulear complex leaves the metal ion and then the resulting four-coordinated complex can be dimerized. As can be seen in Figures 3 and 4(a) in these dinuclear complexes, the hydroxyl group of the 70 hydroxypropoyl arm is not coordinated to the metal ion. Thus the strength of the interaction between hydroxyl group and metal ion was evaluated, to figure out why it leaves the metal ion. However, the value of interaction energy between the metal ion and whole ligand in these complexes was calculated first. As can 75 be seen in Table 4, the values of interaction energies are relatively large and are in the range 629-634 kcal/mol. Thus in all mononuclear complexes the Schiff base ligands are tightly bonded to the central metal ion. However, the data show that the interaction energy between two mononuclear fragments in the ⁸⁰ dinuclear complex $[Cu^{II}L^{H5}]_2(ClO_4)_2$ is very small and only -4.24 kcal/mol (see Table 5). Such a small interaction energy is not surprising as the interacting fragments are both cations. This explains why even in the mass spectra of the dinuclear complexes the major peak corresponds to a mononuclear complex. Indeed, 85 inside the mass spectrometer the dinuclear complex readily breaks into two mononuclear complexes. Two forms, I and II, were considered for one of the mononuclear fragments of the dinuclear complex [Cu^{II}L^{H5}]₂(ClO₄)₂ and the geometry optimised for both them (see Figure 5e and 5f). The difference between the 90 above forms is that in form I the hydroxyl group is not coordinated to the metal ion but is indeed coordinated in form II. The data showed that the energy difference between two above forms is only -2.57 kcal/mol. Thus the interaction between the hydroxyl group and the central metal ion seems to be very weak. 95 This means that the hydroxyl group simply leaves the metal ion, resulting in four-coordinated copper complexes which can be dimerized. This is the reason why in mass spectra of all complexes there is a very small peak corresponding to a dinuclear complex.

membered chelate rings, would be unstable. In order to form the 45 stable structure with square pyramidal geometry, the hypothetical

5

Among the complexes synthesized here, both $[Cu^{II}L^{HS}]_2(CIO_4)_2$ and $[Cu^{II}L^{H4}](CIO_4)$ complexes have the hydroxyl group at the end of a propyl chain. For all the other complexes the hydroxyl group is at the end of an ethyl chain. Indeed, only in the case of $[Cu^{II}L^{HS}]_2(CIO_4)_2$ and $[Cu^{II}L^{H4}](CIO_4)$ do we observe an unstable

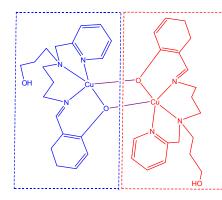

- six-membered chelate ring forming upon coordination of the hydroxyl group. For all other complexes the coordination of the hydroxyl group leads to formation of a more stable fivemembered chelate ring. Thus it seems that the formation of a 15 dinuclear complex in which the hydroxyl group remained
- uncoordinated is quite expectable for both $[Cu^{II}L^{H5}]_2(CIO_4)_2$ and $[Cu^{II}L^{H4}](CIO_4)$ complexes. However X-ray crystal structure

analysis confirmed the formation of a dinuclear complex only in the case of the former complex. Thus two forms I and II for ²⁰ [Cu^{II}L^{H4}](ClO₄) were also considered and optimized (see Figure 5c and 5d). As can be seen in Table 6, the data show that the energy difference between the above forms is about -5.32 kcal/mol. Thus it seems that the interaction energy between the hydroxyl group and metal ion in complex [Cu^{II}L^{H4}](ClO₄) is 25 relatively larger than that in complex [Cu^{II}L^{H5}]₂(ClO₄)₂. On the other hand, the interaction energy between two mononuclear fragments in the dinuclear complex [Cu^{II}L^{H5}]₂(ClO₄)₂ was only -4.24 kcal/mol. The above interaction is larger than -2.57 kcal/mol and less than -5.3 kcal/mol, calculated energy difference between 30 forms I and II in complexes [Cu^{II}L^{H5}]₂(ClO₄)₂ and $[Cu^{II}L^{H4}](ClO_4)$, respectively. This explains why the complex [Cu^{II}L^{H5}]₂(ClO₄)₂ is dimerized while [Cu^{II}L^{H4}](ClO₄) remained mononuclear. For [Cu^{II}L^{H5}]₂(ClO₄)₂, in contrast to $[Cu^{II}L^{H4}](ClO_4)$, the value of interaction energy between two four 35 coordinated fragments is larger than that between the hydroxyl group and central metal ion.

Frozen in the optimized geometry of the [CuL^{ald}]⁺ complex.

⁵ In addition, we believe that the formation of hydrogen bonding between two mononuclear five-coordinated complexes prevents the formation of a dinuclear complex between two four-coordinated fragments. As seen in the previous section the ¹⁰ X-ray crystal structure of the complex [Cu^{II}L^{OMe3}](ClO₄)

- showed that the hydrogen bonding is formed between two mononuclear complexes. Indeed the coordination of the hydroxyl group to the metal ion and then the formation of hydrogen bond between two molecules of such five-15 coordinated complex in [Cu^{II}L^{OMe3}](ClO₄) prevent the
- formation of a dinuclear complex which is formed in the case of $[Cu^{II}L^{H5}]_2(CIO_4)_2$. the value of the interaction between two mononuclear $[Cu^{II}L^{OMe3}](CIO_4)$ complexes due to hydrogen

bonding is about -7.28 kcal/mol (see Fig 4). Interestingly, the ²⁰ latter value is larger than -4.24 kcal/mol, the interaction between two fragments in dinuclear complex [Cu^{II}L^{H5}]₂(ClO₄)₂, and larger than -2.57 and -5.3 kcal/mol, the energy difference between forms I and II of complexes [Cu^{II}L^{H5}]₂(ClO₄)₂ and [Cu^{II}L^{H4}](ClO₄), respectively. Therefore ²⁵ these complexes are special cases in which the intermolecular interactions (herein hydrogen bonding) between two complexes can be stronger than some weak intramolecular metal-donor atom interactions. The formation of a mononuclear complex or a dinuclear one thus depends on relative strength of inter- and ³⁰ intramolecular interactions.

10 Conclusion

In summary, we have reported the successful synthesis of 14 new mononuclear and a few dinuclear Cu(II) complexes by condensation of amines (3-6) with related aldehydes in the presence of Cu(II) metal ion. X-ray crystal structure ¹⁵ determinations of [Cu^{II}L^{napht2}](ClO₄), [Cu^{II}L^{OMe3}](ClO₄), and [Cu^{II}Lⁿ⁴](ClO₄), [Cu^{II}L^{OMe3}](ClO₄), and [Cu^{II}L^{H4}](ClO₄) revealed them to be monomeric, except for the dimeric [Cu^{II}L^{H5}]₂(ClO₄)₂. There is a distorted square pyramidal environment around the central ion in both mononuclear and dinuclear complexes. In this ²⁰ work, emphasis has been put on the examination of structural relationships in the complexation behavior. By comparing crystal structures of the complexes identified to date, all of them use four donor groups of the ligand (three nitrogen atom

and phenoxy oxygen atom) to bind the metal atom and the

25 differences observed is related to hydroxyalkyl arms. These arms are not coordinated to the metal ion in all complexes but in both coordinated and non-coordinated state they remain protonated. Examination of X-ray crystal structures of Cu(II) complexes in the present study show that in the Cu(II) 30 complexes with an ethyl-amino arm, the hydroxypropyl group is bound to the Cu(II) atom, while in the Cu(II) complexes with a propyl-amino arm, the hydroxypropyl arm remains uncoordinated and a dinuclear Cu(II) complex is formed. According to theoretical study, the interaction between the 35 hydroxyl group and the central metal ion seems to be very weak thus the hydroxyl group can leave the metal ion, yielding four-coordinated Cu(II) complexes which can be dimerized. The theoritical study also showed that the formation of a mononuclear complex or a dinuclear one depends on relative 40 strength of inter- and intramolecular interactions. In Cu(II) complexes with an hydroxyethyl arm, there is a stronger interaction between the hydroxyl group and the central metal ion due to the formation of a stable five-membered chelate ring upon the coordination of the hydroxyl group to metal ion. In 45 the case of the Cu(II) complexes with hydroxypropyl arm, an unstable six-membered chelate ring forms upon the coordination of the hydroxyl group - the formation of dinuclear structures is more expectable in this case. Note that both ligands $L^{\rm H5}$ and $L^{\rm H4}$ have a hydroxypropyl arm, but the X-ray 50 crystal structure analysis confirmed the formation of a dinuclear copper complex only in the case of L^{H5}. By comparison of the structures, it seems that both aliphatic linkages are effective on the structure of dimeric complexes. According to theoretical studies, the value of interaction energy between two four coordinate fragments in dinuclear $[Cu^{II}L^{H5}]_2(ClO_4)_2$ complex, in contrast to $[Cu^{II}L^{H4}](ClO_4)$, is

- s larger than that between the hydroxyl group and the central metal ion. Thus we can assume that a mononuclear five coordinated complex forms first, and in a second time the hydroxyl group leaves the metal ion, resulting in a fourcoordinated complex which can be dimerized. In addition of
- ¹⁰ intramolecular interactions, intermolecular interactions are also important in the formation of a mononuclear complex or a dinuclear one. The theoretical study also supported our assumption that the formation of hydrogen bonds between two mononuclear five-coordinated complexes prevents the
- ¹⁵ formation of a dinuclear complex between two four coordinate fragments.

Experimental

General remarks

Pyridine 2-carbaldehyde, 2-Hydroxy-3-methoxybenzaldehyde, 20 2-hydroxybenzaldehyde, 2-hydroxy-1-naphthaldehyde and metal salt were obtained from Aldrich and used without further purification. 3,5-Di-tert-butyl-2-hydroxybenzaldehyde was synthesised according to the literature procedure.⁴² All other chemicals and solvents were of reagent grade and were used as 25 received except for methanol that was dried (Mg) before use.

Caution!

Whilst no problems were encountered in the course of this work, perchlorate mixtures are potentially explosive and should therefore be handled with appropriate care.

30

- Infrared spectra were obtained between 4000 and 400 cm⁻¹ on a Bruker Alpha FT-ATR IR spectrometer with a diamond anvil Alpha-P module for all complexese. UV-vis spectra were recorded on a Jasco V550 spectrophotometer. ESI mass spectra
- ³⁵ were recorded at the University of Otago on a Bruker MicrOTOFQ spectrometer exception for [Cu^{II}L^{H3}](ClO₄), [Cu^{II}L^{OMe3}](ClO₄) and [Cu^{II}L^{tBu3}](ClO₄) complexes that the spectra were recorded using a Kratos-MS- 50T spectrometer. Room temperature magnetic moments were determined using a
- ⁴⁰ Johnson Matthey MSB-MK1 magnetic susceptibility balance. Standard microanalysis for all complexes were carried out by a Perkin–Elmer, CHNS/O elemental analyzer model 2400. ¹H and ¹³C NMR spectra were taken in CDCl₃ on a Jeol 90 MHz spectrometer using Si(CH₃)₄ as an internal standard. Crystals
- ⁴⁵ suitable for X-ray diffraction were obtained by slow diffusion of diethyl ether vapor into methanol or a mixture of methanol and acetonitrile. Single crystal X-ray crystallographic data were collected at 100 K for $[Cu^{II}L^{napht2}](CIO_4)$, $[Cu^{II}L^{OMe3}](CIO_4)$ and $[Cu^{II}L^{H5}]_2(CIO_4)_2$ ($\lambda = 1.54184$) and also at 89 K for

- ⁵⁰ [Cu^{II}L^{H4}](ClO₄) (λ = 0.71073) on a Bruker Kappa APEX II area detector diffractometer (University of Otago), using graphite monochromatic Mo-Kα radiation. In the case of [Cu^{II}L^{H3}](ClO₄) complex, single crystal X-ray crystallographic data was collected at 296 K (λ = 1.54184) on Bruker SMART
- ⁵⁵ BREEZE CCD diffractometer with APEX2 software.⁴³ The data were collected for Lorentz and polarization effects and semi-empirical absorption corrections (SCALE) were applied. The structures were solved by direct or Patterson methods (SHELXS-97)⁴⁴ and refined against all F² data (SHELX-97).⁴⁵
- ⁶⁰ All non-hydrogen atoms were modelled anisotropically except where noted. Unless otherwise specified, hydrogen atoms were inserted at calculated positions and rode on the atoms to which they were attached. In the case of this complex, absorption correction applied to collected data by multi scan, SADAPS
- 65 V2012/1 software. 43 The title compound solved by direct methods 46 using SHELXS-97 and refined with SHELXL-97. 46 The weighted R-factor, wR and goodness of fit S are based on F^2 . The threshold expression of F^2 >2 sigma (F^2) is used only for calculating R-factors. All estimated standard deviations
- 70 (e.s.d's) are estimated using the full covariance matrix. The cell e.s.d's are taken into account individually in the estimation of e.s.d.'s in distances, angles, and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. All non-hydrogen atoms were 75 refined anisotropically and hydrogen atoms were added
- according to the theoretical model. In the case of complex $[Cu^{II}L^{OMe3}](ClO_4)$, we were not able to refine the X-ray crystal structure of this complex exactly.

Computational details

- ⁸⁰ The crystallographic structure of all [CuL^{aldi}]⁺ complexes were fully optimized with def2-SVP basis set at M06⁴⁷ level of theory. The calculated bond lengths and bond angles in optimized complexes were in good agreement with corresponding experimental data. Calculated root mean squares
- ⁸⁵ (RMS) for metal-ligand bond distances were less than 0.055 (see Table 7). The interaction energy between the Cu²⁺ metal ion and the anionic ligand in mononulear complexes was calculated with the following equation:
- $\Delta E = E_{AB} (E_A{}^{AB} + E_B{}^{AB}), \text{ where } E_{AB} \text{ is the minimized energy}$ ⁹⁰ of the [CuL^{aldi}]⁺ complexes and $E_A{}^{AB}$ and $E_B{}^{AB}$ are the energies of Cu²⁺ and L⁻ fragments, respectively, frozen in the geometry of this structure. Also interaction energies between the two mononuclear four coordinte fragments in one dinuclear [Cu^{II}L^{H5}]₂(ClO₄)₂ complex and two five coordinate ⁹⁵ [Cu^{II}L^{OMe3}](ClO₄) complexes bonded through hydrogen bonding were calculated with same formul, where the E_{AB} is the minimized energy of the whole compound and $E_A{}^{AB}$ and $E_B{}^{AB}$ are the energies of the considered fragments. All calculations were performed using the Gaussian09 program.⁴⁸

Synthesis and Characterization

General synthesis of unsymmetrical tripodal amines (3-6)

2-Aminoethanol (1.22 g, 20 mmol) or 3-Aminopropan-1-ol s (1.50 g, 20 mmol) in dry EtOH (100 mL) was added dropwise to a solution of pyridine-2-carbaldehyde (2.14 g, 20 mmol) in dry EtOH (100 mL) over a period of 2 h separately. The mixture was refluxed under stirring for 12 h. Solid sodium borohydride (3.02 g, 80 mmol) was then added slowly and the

- ¹⁰ reaction mixture was stirred for a further 12 h before it was filtered. The filtrate was reduced to 20 mL by rotary evaporation. Water (50 mL) was added and the products extracted with chloroform (3 x 50 mL). The combined extracts were dried over magnesium sulfate, filtered, then taken to
- ¹⁵ dryness by rotary evaporation. The resulting brown oil (1.52 g, 10 mmol (starting with 2-Aminoethano, **I'**) or 1.66 g, 10 mmol (starting with 3-Aminopropan-1-ol, **2'**), 77–86%) was dissolved in acetonitrile (70 mL), solid K₂CO₃ (2.07 g, 15 mmol) added, and the mixture brought to reflux before a solution of N-(4-
- ²⁰ bromobutyl)phthalimide (2.81 g, 10 mmol) was added dropwise to **l'**, or N-(2-bromoethyl)phthalimide (2.53 g, 10 mmol) or N-(3-bromopropyl)phthalimide (2.67 g, 10 mmol) or N-(4-bromobutyl)phthalimide (2.81 g, 10 mmol) in acetonitrile (70 mL) to **2'**. The mixture was refluxed for 48 h and then
- ²⁵ filtered hot. The filtrate was reduced to dryness by rotary evaporation. The brown oil residue was boiled under reflux for 12 h in aqueous HCl (25%, 100 mL) then evaporated to a small volume (ca. 25 mL) under vacuum and cooled in a refrigerator for several hours. The resulting solid was filtered off and
- ³⁰ discarded, and the filtrate evaporated to dryness under vacuum. Water (50 mL) was added to the resulting brown residue and the pH adjusted to 12 with sodium hydroxide before extracting

with chloroform (3 x 50 mL). The combined extract was dried over magnesium sulfate, filtered and the chloroform removed

³⁵ from the filtrate by rotary evaporation to leave the products, 3 6, as brown oils.

- ¹⁰ (s, 1H). ¹³C NMR (CDCl₃, ppm) δ = 23.495; 28.598; 29.624; 40.283; 51.612; 53.237; 59.436; 60.711, 121.218; 122.362; 135.758; 148.031, 158.747.

General synthesis of the complexes

A solution of 0.5 mmol of appropriate aldehyde, 2-hydroxy-3-15 methoxy-benzaldehyde (0.08 g, 0.5 mmol), 2hydroxybenzaldehyde (0.06 g, 0.5 mmol), 3,5-di-tert-butyl-2-

- hydroxybenzaldehyde (0.117 g, 0.5 mmol) or 2-hydroxy-1naphthaldehyde (0.086 g, 0.5 mmol) in methanol (50 ml) and 7 drops of N(Et)₃ were added dropwise to a refluxing solution of 20 Cu(ClO₄)₂.6H₂O (0.184 g, 0.5 mmol) and the corresponding
- amine, 1 (0.098 g, 0.5 mmol) or 2 (0.105 g, 0.5 mmol) or 3 (0.112 g, 0.5 mmol) or 4 (0.105 g, 0.5 mmol) or 5 (0.112 g, 0.5 mmol) or 6 (0.119 g, 0.5 mmol) in the same solvent (50 mL). After refluxing for 12 h, the solution was concentrated in a
- ²⁵ rotary evaporator (EXTREME CAUTION!) at room temperature to ca. 5–10 mL. A small volume of diethyl ether was added slowly, producing powdery precipitate. The powdery Cu(II) products were filtered off, washed with cold diethyl ether and dried under vacuum. Crystalline or powdery
- ³⁰ compounds were obtained by slow diffusion of diethyl ether vapor into a solution of these compounds in methanol or mixture of methanol and acetonitrile, as detailed below. $[C^{ll}L^{naphtl}](ClO_4)$

Recrystallisation of the initial solid from mixture of CH₃OH

- ³⁵ and MeCN in a 5:1 ratio via slow vapour diffusion of Et₂O yields green powder (0.10 g, 79.8 %). Anal. Calc. for C₂₁H₂₂ClCuN₃O₆: C, 49.32; H, 4.34; N, 8.22. Found: C, 49.77; H, 4.55; N, 7.92%. IR (ATR, cm⁻¹) 1616 v (C=N)_{imi}, 1604, 1458 v (C=N)_{py} and v (C=C), 1088, 620 v (ClO₄⁻). ESI-MS
- ⁴⁰ (MeOH, m/z⁺): 411.1 [Cu^{II}L^{napht1}]⁺. UV–Vis. { λ_{max} , nm (ε_{max} , M⁻¹ cm⁻¹)} in CH₃CN: 228 (21097), 390 (2572), 572 (116). Magnetic moment: $\mu_{eff} = 2.2$ B.M. [Gouy]. [Cu^{II}L^{napht2}](ClO₄)

Recrystallisation of the initial solid from CH₃OH via slow

- ⁵⁰ ([Cu^{II}L^{napht2}]⁺₂+H), 949.2 ([Cu^{II}L^{napht2}]⁺₂)ClO₄. UV–Vis. { λ_{max} , nm (ε_{max} , M⁻¹ cm⁻¹)} in CH₃CN: 298 (17419), 387 (6369), 583 (141). Magnetic moment: $\mu_{eff} = 1.72$ B.M. [Gouy]. [Cu^{II}L^{H3}](ClO₄)

Recrystallisation of the initial solid from CH₃OH via slow $\frac{1}{2}$ slow $\frac{1$

⁵⁵ vapour diffusion of Et₂O yields green crystals (0.08 g, 62 %). Anal. Calc. for $C_{19}H_{24}ClCuN_3O_6$: C, 46.63; H, 4.94; N, 8.59. Found: C, 46.62; H, 5.12; N, 8.39%. IR (ATR, cm⁻¹)1619 v (C=N)_{imi}; 1450 v (C=C)_{py}, 1080, 620v (ClO₄). ESI-MS (MeOH, m/z⁺): 389.1 [CuL^{H3}]⁺, 777.2 ([CuL^{H3}]₂-H)⁺, 879.2

- ⁶⁰ ([Cu^{II}L^{H3}]₂+2H)ClO₄⁺. UV–Vis. {λ_{max}, nm (ε_{max}, M⁻¹ cm⁻¹)} in CH₃CN: 224 (137236), 272 (25701), 374 (1377), 463 (314.12), 612 (128.46), 761 (76.53). Magnetic moment: $\mu_{eff} = 1.84$ B.M. [Gouy]. [Cu^{II}L^{OMe3}](ClO₄)
- ⁶⁵ Recrystallisation of the initial solid from mixture of CH₃OH and MeCN in a 1:1 ratio via slow vapour diffusion of Et₂O yields green crystals (0.10 g, 80 %). Anal. Calc. for C₂₀H₂₆ClCuN₃O₇: C, 46.25; H, 5.05; N, 8.09. Found: C, 45.39; H, 5.29; N, 7.72%. IR (ATR, cm⁻¹): 1615 v (C=N)_{imi}; 1600,
- ⁷⁰ 1454 v (C=N)_{py} and v (C=C), 1078, 621 v (ClO₄). ESI-MS (MeOH, m/z⁺): 419.1 [Cu^{II}L^{OMe3}]⁺, 837.3 ([Cu^{II}L^{OMe3}]₂-H)⁺, 939.2 ([Cu^{II}L^{OMe3}]₂+2H)ClO₄⁺. UV-Vis. { λ_{max} , nm (ε_{max} , M⁻¹ cm⁻¹)} in CH₃CN: 238 (31324), 281 (18414), 384 (2537), 483 (303.65), 602 (133.7), 781 (94). Magnetic moment: $\mu_{eff} = 2$ 75 B.M. [Gouy].

 $[Cu^{II}L^{tBu3}](ClO_4)$

Recrystallisation of the initial solid from CH₃OH via slow vapour diffusion of Et₂O yields green powder (0.11 g, 73 %). Anal. Calc. for $C_{27}H_{40}CICuN_3O_6$: C, 53.90; H, 6.70; N, 6.98.

⁸⁰ Found: C, 53.46; H, 6.63; N, 7.32%. IR (ATR, cm⁻¹): 1617 v (C=N)_{imi}; 1441 v (C=C), 1085, 622 v (ClO₄). ESI-MS (MeOH, m/z⁺): 501.2 [Cu^{II}L^{tBu3}]⁺, 1001.5 ([Cu^{II}L^{tBu3}]₂-H)⁺, 1103.4 ([Cu^{II}L^{tBu3}]₂+2H)ClO₄⁺. UV–Vis. { λ_{max} , nm (ε_{max} , M⁻¹ cm⁻¹)} in CH₃CN: 228 (15389), 247 (14363.4), 279 (9711.6), 320

⁸⁵ (3988), 381 (3323), 486 (122), 633 (121), 819 (60). Magnetic moment: $\mu_{\text{eff}} = 1.88$ B.M. [Gouy]. [$Cu^{II}L^{napht3}$](ClO_4)·0.25 CH_3OH

Recrystallisation of the initial solid from mixture of CH_3OH and CH_3CN in a 2:1 ratio via slow vapour diffusion of Et_2O

- ⁹⁰ yields green powder (0.09 g, 68 %). Anal. Calc. for $C_{23,25}H_{27}ClCuN_3O_{6.25}$: C, 51.01; H, 4.97; N, 7.68. Found: C, 51.2; H, 4.92; N, 7.73%. IR (ATR, cm⁻¹, cm⁻¹) 1615 v (C=N)_{imi}; 1604, 1447 v (C=N)_{py} and v (C=C), 1079, 620 v (ClO₄). ESI-MS (MeOH, m/z⁺): 439.1 [Cu^{II}L^{napht3}]⁺, 879.3
- ⁹⁵ ([Cu^{II}L^{napht3}]₂+H)⁺, 979.2 ([Cu^{II}L^{napht3}]₂+2H)ClO₄⁺. UV–Vis. {λ_{max}, nm (ε_{max}, M⁻¹ cm⁻¹)} in CH₃CN: 238 (35335), 311 (17908), 398 (6036), 485 (sh), 600 (157), 770 (98). Magnetic moment: $\mu_{eff} = 2.01$ B.M. [Gouy]. [Cu^{II}L^{H4}](ClO₄)
- ¹⁰⁰ Recrystallisation of the initial solid from a mixture of CH₃OH and CH₃CN in a 1:1 ratio via vapour diffusion of Et₂O yields green crystals (0.178 g, 75 %). Anal. Calc. for C₁₈H₂₂ClCuN₃O₆: C, 45.48; H, 4.66; N, 8.84. Found: C, 45.42; H, 4.93; N, 9.02%. IR (ATR, cm⁻¹): 1632 v (C=N)_{imi}, 1600,
- ¹⁰⁵ 1445 v (C=N)_{py} and v (C=C), 1071, 619 v (CIO₄). ESI-MS (MeOH, m/z⁺): 375.1 [Cu^{II}L^{H4}]⁺. UV–Vis { λ_{max} , nm (ε_{max} , M⁻¹ cm⁻¹)} in CH₃CN: 222 (18271), 244 (17469), 266 (14079), 371 (3402), 587 (169). Magnetic moment: μ_{eff} = 1.82 B.M. [Gouy]. [Cu^{II}L^{OMe4}](ClO₄)
- ¹¹⁰ Recrystallisation of this solid from CH₃OH via slow vapour diffusion of Et₂O yields green crystals (0.095 g, 75 %). Anal. Calc. for C₁₉H₂₄ClCuN₃O₇: C, 45.15; H, 4.79; N, 8.31. Found: C, 45.29; H, 4.60; N, 8.40%. IR (ATR, cm-1); 1622 v (C=N)_{imi}; 1444 v (C=N)_{py} and v (C=C), 1068, 620 v (ClO₄). ESI-MS
- ¹¹⁵ (MeOH, m/z⁺): 405.1 [Cu^{II}L^{OMe4}]⁺. UV–Vis. { λ_{max} , nm (ε_{max} , M⁻¹ cm⁻¹)} in CH₃CN: 205 (22476), 240 (17281), 270 (12011), 382 (2324), 575 (174). Magnetic moment: $\mu_{eff} = 1.90$ B.M. [Gouy].

$[Cu^{II}L^{tBu4}](ClO_4) \cdot 0.1CH_3OH$

Recrystallisation of the initial solid from CH₃OH via slow vapour diffusion of Et₂O yields green powder (0.115 g, 78 %). Anal. Calc. for $C_{26.1}H_{38.4}ClCuN_3O_{6.1}$: C, 53.06; H, 6.55; N, $\stackrel{5}{}$ 7.11. Found: C, 53.16; H, 6.63; N, 7.02%. IR (ATR, cm-1):

- 1629 v (C=N)_{imi}; 1612, 1462 v (C=N)_{py} and v C=C), 1070, 620 v (ClO₄). ESI-MS (MeOH, m/z⁺): 487.2 [Cu^{II}L^{Bu4}]⁺. UV–Vis. {λ_{max}, nm (ε_{max}, M⁻¹ cm⁻¹)} in CH₃CN: 227 (17049), 248 (14636), 274 (10800), 383 (3105), 630 (155). Magnetic ¹⁰ moment: μ_{eff} = 1.95 B.M. [Gouy].
- $[Cu^{II}L^{napht4}](ClO_4)$

Recrystallisation of the initial solid from mixture of CH₃OH and CH₃CN in a 3:1 ratio via slow vapour diffusion of Et₂O yields green powder (0.191 g, 73 %). Anal. Calc. for

- ²⁰ in CH₃CN: 226 (27244), 237 (sh), 248 (sh), 287 (10913), 313 (8927), 383 (4194), 574 (162). Magnetic moment: $\mu_{eff} = 1.86$ B.M. [Gouy].

 $[Cu^{II}L^{H5}]_2(ClO_4)_2$

Recrystallisation of the initial solid from mixture of CH₃CN ²⁵ and CH₃OH in a 5:1 ratio via vapour diffusion of Et₂O yields

- ²⁵ and CH₃OH in a 5:1 ratio via vapour diffusion of Et₂O yields green crystals (0.342 g, 70 %). Anal. Calc. for $C_{38}H_{48}Cl_2Cu_2N_6O_{12}$: C, 46.63; H, 4.94; N, 8.59. Found: C, 46.72; H, 4.90; N, 9.01%. IR (KBr disc, cm⁻¹): 1620 v (C=N)_{imi}; 1596, 1440 v (C=N)_{py} and v C=C), 1069, 619 v
- ³⁰ (ClO₄). ESI-MS (MeOH, m/z⁺): 389.1 [Cu^{II}L^{H5}]⁺, 879.1 ([Cu^{II}L^{H5}]₂ClO₄+2H)⁺. UV–Vis. { λ_{max} , nm (ε_{max} , M⁻¹ cm⁻¹)} in CH₃CN: 257 (6806), 305 (2924), 404 (379), 598 (92). Magnetic moment: μ_{eff} = 1.58 B.M per Cu atom [Gouy]. [Cu^{II}L^{OMe5}]₂(ClO₄)₂
- ²⁵ Recrystallisation of the initial solid from mixture of CH₃OH and MeCN in a 5:1 ratio via slow vapour diffusion of Et₂O yields green powder (0.348 g, 67 %). Anal. Calc. for $C_{40}H_{52}Cl_2Cu_2N_6O_{14}$: C, 46.25; H, 5.05; N, 8.09. Found: C, 46.17; H, 5.25; N, 8.4%. IR (ATR, cm⁻¹): 1620 v (C=N)_{imi};
- ⁴⁰ 1444 ν (C=C), 1078, 620 ν (ClO₄). ESI-MS (MeOH, m/z⁺): 419.1 [Cu^{II}L^{OMe5}]⁺, 939.2 ([Cu^{II}L^{OMe5}]₂+2H)ClO₄⁺. UV–Vis. {λ_{max}, nm (ε_{max}, M⁻¹ cm⁻¹)} in CH₃CN: 258 (9704), 313 (3700), 406 (754), 587 (122). Magnetic moment: μ_{eff} = 1.52 B.M. per Cu atom [Gouy].
- 45 $[Cu^{II}L^{tBu5}]_2(ClO_4)_2$

Recrystallisation of the initial solid from CH₃OH via slow vapour diffusion of Et₂O yields green crystals (0.189 g, 63 %). Anal. Calc. for $C_{54}H_{80}Cl_2Cu_2N_6O_{12}$: C, 53.90; H, 6.70; N, 6.98. Found: C, 53.65; H, 6.93; N, 7.22%. IR (ATR, cm-1): 1624 v

⁵⁰ (C=N)_{imi}; 1600, 1440 v (C=N)_{py} and v (C=C), 1074, 620 v (ClO₄). ESI-MS (MeOH, m/z⁺): 501.2 [Cu^{II}L^{tBu5}]⁺. UV–Vis. { λ_{max} , nm (ε_{max} , M⁻¹ cm⁻¹)} in CH₃CN: 210 (127302), 229 (14206), 248 (13790), 275 (9945), 306 (4208), 383 (2838), 610 (166). Magnetic moment: $\mu_{eff} = 1.32$ B.M. per Cu atom [Gouy]. ⁵⁵ [Cu^{II}L^{napht5}]₂(ClO₄)₂

Recrystallisation of the initial solid from CH₃OH via slow vapour diffusion of Et₂O yields green powder (0.177 g, 66 %). Anal. Calc. for $C_{46}H_{52}Cl_2Cu_2N_6O_{12}$: C, 51.21; H, 4.86; N, 7.79. Found: C, 51.62; H, 4.93; N, 8.03%. IR (ATR, cm⁻¹): 1620 v

- ⁶⁰ (C=N)_{imi}; 1602, 1449 v (C=N)_{py} and v (C=C), 1079, 620 v (CIO₄⁻). ESI-MS (MeOH, m/z⁺): 439.1 [Cu^{II}L^{napht5}]⁺, 979.2 ([Cu^{II}L^{napht5}]₂+2H)CIO₄⁺. UV–Vis. { λ_{max} , nm (ϵ_{max} , M⁻¹ cm⁻¹)} in CH₃CN: 224 (36505), 322 (10751), 382 (4649), 402(sh), 599 (140). Magnetic moment: μ_{eff} = 1.66 B.M. Cu atom [Gouy]. ⁶⁵ [Cu^{II}L^{H6}](CIO₄)
- Recrystallisation of the initial solid from CH₃OH via slow vapour diffusion of Et₂O yields green powder (0.16 g, 65 %). Anal. Calc. for C₂₀H₂₆ClCuN₃O₆: C, 47.71; H, 5.21; N, 8.35. Found: C, 47.62; H, 5.42; N, 8.19%. IR (ATR, cm⁻¹) 1624 v
- ⁷⁰ (C=N)_{imi}; 1446 v (C=C), 1049, 620 v (ClO₄). ESI-MS (MeOH, m/z⁺): 403.1326 [CuL^{H6}]⁺. UV–Vis. { λ_{max} , nm (ε_{max} , M⁻¹ cm⁻¹}] in CH₃CN: 223 (49480), 273 (15334), 307 (5202), 371 (3433), 619 (136). Magnetic moment: $\mu_{eff} = 1.78$ B.M. [Gouy]. [Cu^{II}L^{OMe6}](ClO₄). 0.25 CH₃OH
- ⁷⁵ Recrystallisation of the initial solid from mixture of CH₃OH and MeCN in a 1:1 ratio via slow vapour diffusion of Et₂O yields green powder (0.18 g, 68 %). Anal. Calc. for $C_{21.25}H_{29}ClCuN_3O_{7.25}$: C, 47.14; H, 5.40; N, 7.76. Found: C, 47.24; H, 5.39; N, 7.72%. IR (ATR, cm⁻¹): 1615 v (C=N)_{imi};
- ⁸⁰ 1446 v (C=C), 1074, 625 v (ClO₄). ESI-MS (MeOH, m/z⁺): 433.1411 [Cu^{II}L^{OMc6}]⁺. UV–Vis. { λ_{max} , nm (ε_{max} , M⁻¹ cm⁻¹)} in CH₃CN: 204 (23919), 237 (21533), 281 (13442), 381 (3564), 594 (145). Magnetic moment: $\mu_{eff} = 1.74$ B.M. [Gouy]. [Cu^{II}L^{tBu6}](ClO₄). 0.25H₂O
- ⁸⁵ Recrystallisation of the initial solid from CH₃OH via slow vapour diffusion of Et₂O yields green powder (0.19 g, 63 %). Anal. Calc. for $C_{28}H_{42.5}ClCuN_3O_{6.25}$: C, 54.23; H, 6.91; N, 6.78. Found: C, 54.23; H, 6.91; N, 6.78%. IR (ATR, cm⁻¹): 1613 v(C=N)_{imi}; 1460 v (C=C), 1081, 621 v (ClO₄). ESI-MS
- ⁹⁰ (MeOH, m/z⁺): 515.2532 [Cu^{II}L^{tBu6}]⁺. UV–Vis. { λ_{max} , nm (ε_{max} , M⁻¹ cm⁻¹)} in CH₃CN: 203 (19536), 228 (15706), 248 (14105), 280 (9412), 328 (3974), 384 (3135), 507 (165), 621 (164). Magnetic moment: $\mu_{eff} = 1.92$ B.M. [Gouy]. [Cu^{II}L^{napht6}](ClO₄)
- ⁹⁵ Recrystallisation of the initial solid from mixture of CH₃OH and CH₃CN in a 3:1 ratio via slow vapour diffusion of Et₂O yields green powder (0.19 g, 69 %). Anal. Calc. for $C_{24}H_{28}ClCuN_3O_6$: C, 52.08; H, 5.10; N, 7.59. Found: C, 52.42; H, 5.22; N, 7.33%. IR (ATR, cm⁻¹, cm⁻¹) 1622 v (C=N)_{imi};
- ¹⁰⁰ 1597, 1445 v (C=N)_{py} and v (C=C), 1051, 619 v (ClO₄). ESI-MS (MeOH, m/z⁺): 453.1437 [Cu^{II}L^{napht6}]⁺. UV–Vis. { λ_{max} , nm (ε_{max} , M⁻¹ cm⁻¹)} in CH₃CN: 227 (26485), 235 (26573), 311 (12151), 383 (4209), 399 (4221), 588 (112). Magnetic moment: μ_{eff} = 2.02 B.M. [Gouy].

- ^d Department of Physics, Arts and Sciences Faculty, Aksaray University, TR-68100, Aksaray, Turkey
- † Electronic Supplementary Information (ESI) available: [1HNMR,
- ¹³CNMR and IR spectra of amines (3-6) (Figures S1-S12), IR spectra
 ¹⁰ of complexes (Figures S13-S30), Mass spectra of complexes (Figures S31-S48). Crystallographic data for the crystal structure analyses have been deposited with the Cambridge Crystallographic Data Centre, CCDC no. (968863), for [Cu^{II}L^{napht2}](ClO₄), (968865), for [Cu^{II}L^{H3}](ClO₄), (1002225), for [Cu^{II}L^{OMe3}](ClO₄), (1002229), for 15 [Cu^{II}L^{H4}](ClO₄) and (1002230), for [Cu^{II}L^{H5}]₂(ClO₄)₂. Copies of this
- ¹⁵ [Cu^{II}L^{H4}](ClO₄) and (1002230), for [Cu^{II}L^{H5}]₂(ClO₄)₂. Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union road, Cambridge, CB2 1EZ, UK (fax: +44 1223 336033; mail:deposit@ccdc.cam.ac.uk).]. See DOI: 10.1039/b000000x/
