This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
Oxoiron(IV)-mediated Baeyer-Villiger oxidation of cyclohexanones generated by dioxygen with co-oxidation of aldehydes.

Dóra Lakk-Bogáth, Gábor Speier, and József Kaizer*

In this communication we describe a detailed mechanistic studies on the [Fe(II)(CH$_3$CN)(N$_4$Py)(ClO$_4$)]ClO$_4$-catalyzed (N$_4$Py = N,N-bis(2-pyridylmethyl)-N,N-bis(2-pyridyl)methylamine) Baeyer-Villiger oxidation of cyclohexanones by dioxygen with cooxidation of various aldehydes, including the kinetics on the formation and the reactivity of the trapped and spectroscopically characterized oxoiron(IV) intermediate.

Baeyer-Villiger oxidation is one of the most important reactions in organic chemistry because the lactones or esters are important industrial intermediates in the production of polymers, pharmaceuticals and herbicides. The most common oxidants used for this reaction are peroxycarboxylic acids. Over the past four decades transition metal complexes of a variety of ligand systems like porphyrins, Schiff bases, isoindolines, polypyridines etc. have been reported as active catalysts for the catalytic oxygen transfer reactions, and their catalytic cycles often involve oxoiron(IV) intermediates as oxidants. Within the past decade more than 60 oxoiron(IV) complexes, including S=1 and S=2 ground states, have been produced by reactions of precursor complexes with externally prepared oxidizing compounds (in which oxygen is already partly reduced) such as iodosylbenzene (PhIO), m-chloroperoxybenzoic acid (m-CPBA), and hydroperoxides (H$_2$O$_2$ and RO$_2$H). However, only few examples exist for their generation by activating dioxygen. Since the molecular oxygen is a cheap, environmentally clean and readily oxidant, the use of O$_2$ as the primary oxidant is of fundamental importance. Oxoiron(IV) species can be prepared in solvent mixtures of CH$_3$CN/alcohols or CH$_3$CN/ethers, furthermore in the presence of an electron donor (dihydroxynicotinamide adenine dinucleotide (NADH) analogue or BPh$_4$) and proton source (HClO$_4$). Dioxygen activation using an aldehyde as a reductant is a very simple and practical oxidative system that is able to epoxidize alkenes, Baeyer-Villiger oxidation of ketones and oxidation of alcohols and of some hydrocarbons. These processes proceed via a free radical chain mechanism, and without transition metal catalyst are often of low efficiency and selectivity. Metal complexes depending on their reduction power can accelerate or inhibit the above processes. There are some reports on the aerobic Baeyer-Villiger oxidation of ketones to esters or $\varepsilon$-lactons catalysed by iron catalysts with aldehyde as reductant, but until now, no direct evidence for the involvement of a high-valent oxoiron species in the catalytic process.

We have found that complex [Fe(II)(CH$_3$CN)(N$_4$Py)(ClO$_4$)]$_2$ (I) (N$_4$Py = N,N-bis(2-pyridylmethyl)-N,N-bis(2-pyridyl)methylamine) highly selectively and efficiently catalyse the Baeyer-Villiger (B.-V.) oxidation of cyclohexanone derivatives to $\varepsilon$-caprolactones with molecular oxygen in the presence of various aldehydes such as isobutyraldehyde and benzaldehyde (Fig. 1, and Table S1, ESI†).

![Fig. 1. Yields without and with catalyst for the 1-catalysed B.-V. oxidation of cyclohexanones with benzaldehyde in MeCN at 60°C under oxygen atmosphere for 15 hours. [I]$_0$ = 1.00 x 10$^{-3}$ M, [cyclohexanone derivatives]$_0$ = 1.00 x 10$^{-2}$ M, [benzaldehyde]$_0$ = 1.50 x 10$^{-3}$ M.](image-url)
The reactions were carried out in MeCN at 298, 323, 333 and 343 K. The optimum conditions used for the cyclohexane oxidation were: catalyst, substrate and aldehyde in a molar ratio of 1 : 1000 : 15000, respectively at 333 K in acetonitrile solution under dioxygen. The consumption of the starting ketones and formation of oxidized products were monitored by GC or GC-MS in the presence of inert internal standard (naphthalene) (Fig. S1-S6, ESIF). The oxidation in the presence of isobutyraldehyde proceeds with moderate conversion (6.2% (5h) and 16.4% (15h) at 333 K). The highest conversions are attained with benzaldehyde, 34% and 73% after 5 and 15 h, respectively. In case of the Fe(m-CPBA)-containing system the oxidation occurs with much higher yields (59.1% (5h) and 100% (15h) at 333 K), the yields without catalyst are 16.8 and 92.3% after 5 and 15h, respectively (Table S1, ESIF). It means that the conversion can be increased in both cases by the use of I, compared to the classical B.-V. reaction (Fig. S7 and S8, ESIF). Complex I may have a dual effect, it can serve as an initiator and catalyst too. The relative reactivity of substrates is in the following order: cyclohexanone (73%) > 2Mevcyclohexanone (62.5%) > 4Mevcyclohexanone (53%) > 4Bu-cyclohexanone (18%) > 3Me-cyclohexanone (15.5%), 3- and 5-methyl-ε-caprolactone (1:1) ([cyclohexanone] = 116(M+, 7.7), 114(M+, 4.8). The 18O-ε-lactone derivative gave a molecular ion at m/z 116 (114 + 2), showing that one of the 18O atom of 18O2 is incorporated into the cyclohexanone ring. The relative abundance of m/z 116 to that at m/z 114 (~62%) parallels the 18O enrichment used in the experiment (Fig. S2, and Table S1, ESIF). The second 18O atom of 18O2 can be found in the forming benzoic acid: m/z 124(M+, 64.6), 122(M+, 54.7). The smaller value of the relative abundance (54% compared to 62%) can be explained by water exchanged reaction. Spectral investigations on the catalytic system above have confirmed the formation of oxoiron(IV) species (Fig. 3, and Fig. S9, ESIF). The steady-state concentration of [Fe(IV)=O(N4Py)]2+ (2) was determined to be ~20% by comparing the intensity of the absorption band at 693 nm with the known ε value of 2.[12a,b]

In order to prove that cyclohexanone has been oxygenated, we carried out the reaction with a mixture of 18O2 and 16O2 60 : 40%). Analysis of the GC-MS spectra of the products using 18O-labeled compounds gave an answer to this question. After 24 h of stirring the reactants at 298 K, GC-MS analysis of the reaction mixture shows the presence of 18O- and 16O-ε-lactone in the appropriate ratio: m/z 116(M+, 7.7), 114(M+, 4.8). The 18O-ε-lactone derivative gave a molecular ion at m/z 116 (114 + 2), showing that one of the 18O atom of 18O2 is incorporated into the cyclohexanone ring. The relative abundance of m/z 116 to that at m/z 114 (~62%) parallels the 18O enrichment used in the experiment (Fig. S2, and Table S1, ESIF). The second 18O atom of 18O2 can be found in the forming benzoic acid: m/z 124(M+, 64.6), 122(M+, 54.7). The smaller value of the relative abundance (54% compared to 62%) can be explained by water exchanged reaction. Spectral investigations on the catalytic system above have confirmed the formation of oxoiron(IV) species (Fig. 3, and Fig. S9, ESIF). The steady-state concentration of [Fe(IV)=O(N4Py)]2+ (2) was determined to be ~20% by comparing the intensity of the absorption band at 693 nm with the known ε value of 2.[12a,b]

![Fig. 2. Hammett plot for the para-substituted benzaldehydes in the B.-V. reactions without I (black), and with I (white) in MeCN at 60 °C. Inset: yields in the reactions without I (white), and with I (black), [I]0 = 1.00 × 10−3 M, [cyclohexanone]0 = 1.00 × 10−3 M, [aldehyde]0 = 1.50 × 10−3 M under O2.](image)

To get insight into the formation of 2 generated by dioxygen plus benzaldehydes, which serve as oxygen acceptors, detailed kinetic studies were carried out at 293 K, in MeCN, without cyclohexanones. The kinetic profile of the reaction is given in Fig. 4. Addition of benzaldehyde at room temperature to acetonitrile solution of the complex 1 under air results in rapid changes in colour from red to green. Similar spectral behaviour can be observed during the reaction of I with m-CPBA (Fig. S10, ESIF), where the formation of 2 can be drawn by oxene transfer between the precursor complex and the oxidant. Influence of the structure and electronic properties of the aldehyde was also studied on the formation reaction of 2. Isobutyraldehyde gave ~10% yield of 2 (Fig. S11, ESIF). Upon using para-benzaldehydes with electron donating groups the yields were increased remarkably (Fig. S11, ESIF). Rate constants (kobs) determined from these plots showed a good
linear correlation ($r = 0.99$, $n = 4$) with the Hammett substituent parameters ($\sigma = -1.61$, Fig. S12, ESI†).

Time analysis of these reactions showed an induction period (lengths are dependent on the amount of dioxygen, benzaldehyde, and complex 1 concentration), and after that a first order rate law was observed. The partial rate orders of the reaction were investigated by plotting the initial concentrations against the reaction rates, which gave straight lines, suggesting an overall third order rate law of $d[cyclohexanone]/dt = k_3 [aldehyde][I][O_2]$ with a third-order rate constant $k_3 = 34 \pm 2$ M$^{-2}$s$^{-1}$ in MeCN at 298 K (Fig S13-S18, Table S2 and S3, ESI†). The dependence of $k_3$ on temperature ($T = 293$ to 308 K) gave the activation parameters $\Delta H^\ddagger = 44$ kJ mol$^{-1}$ and $\Delta S^\ddagger = -109$ J mol$^{-1}$K$^{-1}$ (Table S3, Fig. S19, ESI†).

Finally, to get direct evidence for the involvement of the high-valent oxoiron(IV) species in the Baeyer-Villiger oxidation, the reaction of 2 with various cyclohexanone derivatives was investigated. The oxoiron(IV) was generated by reaction of 1 with PhIO,$^{12}$ and its reaction with cyclohexanones was measured as a function of the concentration of added cyclohexanone derivatives (Fig. 5 and 6). It was found that the electrophilic oxoiron(IV) is able to oxidize the cyclohexanone derivatives to the corresponding $\alpha$-caprolactones, excluding it’s nucleophile attack on the carbonyl group. Since no reaction has been observed for acetophenone and benzophenone, this indicates clearly that the conjugation of the carbonyl group decreases the reactivity of the ketone.$^{11a}$ The traces could be fitted with a first-order kinetic law, with respect to 2, and the calculated $k_{obs}$ values for different concentrations of the appropriate substrate are reported in Table S4 (ESI†). The relative reactivity of substrates is in the following order: cyclohexanone > 2Me-cyclohexanone > 4Me-cyclohexanone > 4Bu-cyclohexanone > 3Me-cyclohexanone, which is the same trend, that was found for the catalytic system (Fig. 5, and Table S4, ESI†). Kinetic experiments revealed 1st-order dependence on both the oxoiron(IV) and the substrate concentration with $k_2 = 1.48 \pm 0.04$ M$^{-1}$s$^{-1}$, $\Delta H^\ddagger = 41$ kJ mol$^{-1}$ and $\Delta S^\ddagger = -111$ J mol$^{-1}$K$^{-1}$ at 298 K (Table S4, Fig. S20-21, ESI†). The low activation enthalpies and the large negative activation entropies are typical of associative processes.

In summary, a mechanism for the iron(II)-catalysed Baeyer-Villiger oxidation of cyclohexanones by O$_2$ and aldehyde has been proposed (Scheme 1). It is well known that autoxidation rates of aldehydes are very high with long propagation chains even at room temperature. In the absence of 1 the formation of the $\alpha$-caprolactones are very high with long propagation chains even at room temperature. In the absence of 1 the formation of the $\alpha$-caprolactones are very high with long propagation chains even at room temperature. In the absence of 1 the formation of the $\alpha$-caprolactones are very high with long propagation chains even at room temperature.
oxygen acceptors and dioxygen as oxidant. The experimental results clearly indicated the formation of a high-valent metal-oxo intermediate (Fe\textsuperscript{IV}=O), and its role in the oxidation process.

In conclusion, a novel catalytic method for the Baeyer-Villiger oxidation of cyclohexanone derivatives has been investigated with non-heme iron(II) complex as catalyst, aldehydes as oxygen acceptors and dioxygen as oxidant. The experimental results clearly indicated the formation of a high-valent metal-oxo intermediate (Fe\textsuperscript{IV}=O), and its role in the oxidation process.

Oxoiron(IV)-mediated Baeyer-Villiger oxidation of cyclohexanones generated by dioxygen with co-oxidation of aldehydes.

Dóra Lakk-Bogáth, Gábor Speier, and József Kaizer*

Mechanistic studies on the Fe(II)-catalyzed Baeyer-Villiger oxidation is described, including the formation and the reactivity of the trapped oxoiron(IV) intermediate.
