1,3-Dipolar Cycloadditions of azomethine imines

Carmen Nájera,^{*} José M. Sansano and Miguel Yus

Azomethine imines are considered 1,3-dipoles of the aza-allyl type which are transient intermediates and should be generated in situ but can be also stable and isolable compounds. They react with electron-rich and electron-poor olefins as well as with acetylenic compounds and allenoates mainly by a [3+2] cycloaddition but they can also take part in [3+3], [4+3], [3+2+2] and [5+3] with different dipolarophiles. These 1,3-dipolar cycloadditions (1,3-DC) can be performed under thermal or microwave conditions but also using metallo- and organocatalytic systems. In recent years enantiocatalyzed 1,3-dipolar cycloadditions have been extensively considered and applied to the synthesis of a great variety of dinitrogenated heterocycles with biological activity. Acyclic azomethine imines derived from mono and disubstituted hydrazones could be generated by prototropy under heating or by means of Lewis or Brønsted acids to give, after [3+2] cycloadditions, pyrazolidines and pyrazolines. Cyclic azomethine imines, incorporating a C-N bond in a ring, such as isoquinolinium imides are the most widely used dipoles in normal and inverse-electron demand 1,3-DC allowing the synthesis of tetrahydro-, dihydro- and unsaturated pyrazolo[1,5-a]isoquinolines in racemic and in enantioenriched form with interesting biological activity. Pyridinium and quinolinium imides give the corresponding pyrazolopyridines and indazolo[3,2alisoquinolines, respectively. In the case of cyclic azomethine imines with a N-N bond incorporated in a ring N-alkylidene-3-oxo-pyrazolidinium ylides are the most popular stable and isolated dipoles able to form dinitrogen-fused saturated and unsaturated pyrazolopyrazolones as racemic or enantiomerically enriched compounds present in many pharmaceuticals, agrochemicals and other useful chemicals.

Departamento de Química Orgánica, Facultad de Ciencias, and Centro de Innovación en Química Avanzada (ORFEO-CINQA), Universidad de Alicante, Apdo. 99, 03080 Alicante, Spain

1 General introduction

Azomethine imines are 1,3-dipoles of the allylic type, which present two type of resonance structures, iminium imide and diazonium ylide.¹⁻⁴ They are readily accessible as stable compounds or as intermediates for the synthesis of diverse dinitrogenated heterocycles by means of 1,3-dipolar cycloadditions (1,3-DC) under thermal or catalyzed conditions.²⁻¹² Numerous type of pharmaceuticals, agrochemicals and other biologically active compounds can be prepared by means of different type of [3+2] cycloadditions, mainly with alkenes and alkynes, but also high order cycloadditions, such as [3+3], [4+3] and [3+2+3] have been recently developed. The asymmetric processes have been performed using chiral substrates, chiral metal complexes or organocatalysts.¹³⁻¹⁵ In this review we summarized the diverse type of azomethine imines (Scheme 1) which have been used as 1,3-dipoles in the last ten year, not only in racemic, but also in asymmetric processes. They have been classified according to the Schantl's review¹⁰ covering literature until 2003.

Acyclic azomethine imines

Azomethine imines with a N-N bond incorporated in a ring

Scheme 1 Typical azomethine imines.

2 Acyclic azomethine imines

These types of dipoles have been postulated as intermediates in [3+2] cycloaddition reactions and are derived from hydrazones and carbazates (Scheme 1) leading to pyrazolines and pyrazolidines, and their derivatives. The corresponding precursors can be prepared from monosubstituted and 1,2-disubstituted hydrazines.

2.1 From monosubstituted hydrazines

Azomethine imines derived from acyclic hydrazones are generated easily upon 1,2-prototropy either under heating by Lewis acid catalysis or by protonation, and can be trapped with different dipolarophiles to afford five-membered dinitrogenated heterocycles through inter- and intramolecular cycloadditions.¹⁶⁻¹⁸ Normally, electron-deficient dipolarophiles are used, but also simple alkenes in the case of intramolecular processes.¹⁰ A recent intramolecular process has been applied to the synthesis of androstenoarylpyrazolines **3** using BF₃·OEt₂ as Lewis acid, previously used for intermolecular cycloadditions (Scheme 2).²⁰ The reaction takes place stereoselectively at 0 °C in high yields from the corresponding hydrazones **1** by a BF₃-promoted formation of intermediate azomethine imines **2**.

Scheme 2 Intramolecular BF₃-catalyzed [3+2]-cycloaddition of hydrazones with alkenes.

Three-component or consecutive intermolecular 1,3-DC of azomethine imines with α oxoketenes **5** has been performed under thermal conditions. Both, hydrazones and dipolarophiles
are generated in situ, affording the corresponding pyrazolidinones **6** in a stereoselective manner
(Scheme 3).^{21a} Intermediate dipolarophiles **5** are generated from 2-diazo-1,3-diones **4** under

Organic & Biomolecular Chemistry Accepted Manuscript

microwave heating. When isatins are used as carbonyl precursor the corresponding spirooxindoles 7 are obtained in a stereoselective manner (Scheme 3).

Scheme 3 1,3-DC of hydrazones with α -oxoketenes.

Recently, a microwave-assisted intramolecular 1,3-DC of azomethine imines, in situ generated from indole-2-carboxaldehydes **8** and phenylhydrazine has been described. This process takes place in the presence of HCl as additive in ethanol, providing [*a*]-annelated pyrazolopyrroloindoles **9** in a regio- and stereoselective manner (Scheme 4).^{21b} The reaction in presence of other additives such as AcOH, BF₃·OEt₂ or iodine gave either lower yields or no reaction.

Scheme 4 Synthesis of pyrazolopyrrolinodoles by intramolecular 1,3-DC.

The stereocontrolled synthesis of *cis*-cyclopentanopyrazolidines has been carried out from the α -methoxy- α , β -unsaturated ester **10** bearing an α -keto ester at the end of the chain (Scheme 5).²² In the case of using thiosemicarbazide the intermediate azomethine imine is generated under heating giving the tricyclic thiohydantion **11**. *N*-Acyl or *N*-alkoxycarbonyl hydrazines gave under thermal conditions the corresponding cycloadducts **12** in good yields (Scheme 5). This approach was previously described by the same group to prepare potential precursors of palau'amine (Scheme 6).²³

Scheme 5 Synthesis of cis-cyclopentanopyrazolidines by intramolecular 1,3-DC.

Scheme 6 Synthesis of a precursor of palau'amine.

The high stereoselectivity observed in these cycloadditions can be explained by formation of a chairlike transition state **15**, which favors the overlap between the π -orbitals of the dipole and dipolarophile (Scheme 7).

Scheme 7 Proposed mechanism for the formation of cycloadducts 12.

Alternatively, it was possible to prepare the corresponding hydrazones **16** from **10** using a catalytic amount of HCl in ethanol at room temperature, and then the 1,3-DC takes place at ambient temperature in the presence of one equivalent of FeCl₃ in dichloromethane, giving products **12** in good yields (Scheme 8).²²

Scheme 8 FeCl₃-Promoted 1,3-DC of hydrazones 16.

Organic & Biomolecular Chemistry

The same chiral catalyst formed by $Zr(Oi-Pr)_4$ and Binol **19** has been used in the intermolecular [3+2] cycloaddition of benzoylhydrazones **20** and electron-rich alkenes like the ketene dimethyl dithioacetal **21**. The corresponding 3,5-disubstituted pyrazolidines **22** were obtained in good yields and enantioselectivities (Scheme 10).²⁵ In the case of vinyl ethers or thioethers **23** compounds **24** were obtained in low to moderate diastereoselectivity and high enantioselectivity. Samarium diiodide reduction of **24** afforded the corresponding 1,3-diamines, whereas LiAlH₄ gave pyrazolidines.

Scheme 10 Asymmetric intermolecular 1,3-DC of benzoylhydrazones 20.

A chiral silicon Lewis acid has been used in the intermolecular 1,3-DC of benzoylhydrazones **20** with vinyl ethers **23** (Scheme 11).²⁶ The process needs 1.5 equivalents of compound **25**, derived from pseudoephedrine, to take place giving the corresponding pyrazolidines **24** at room temperature in high *trans*-diastereoselectivity and excellent ee. The intermediacy of the complex **26**, isolated and characterized by X-ray crystallography,²⁷ explain the approach of the ether by the *Si* face of the hydrazone (**27**). Samarium diiodide reduction of pyrazolidines **22** gave the corresponding *anti*-1,3-diamines.

Scheme 11 Chiral silicon Lewis acid mediated 1,3-DC of benzoylhydrazones 20.

Hydrazones derived from ethyl glyoxylate and aliphatic or aromatic aldehydes react with cyclopentadiene (**28**) at room temperature in the presence of TMSOTf (10 mol%) as catalyst. The enantiocatalytic process was next assayed with an in situ generated Binol-phosphate derived silicon Lewis acid from **30** and Ph₂SiCl₂ (Scheme 12).²⁸ Cycloadduct **29** was obtained in high *syn/anti* diastereomeric ratio (95:5) and up to 89% ee, but in a low yield (13%).

Scheme 12 First catalytic asymmetric 1,3-DC of hydrazones 20 with cyclopentadiene.

The asymmetric Brønsted acid catalyzed 1,3-DC of benzoylhydrazones **20** could be efficiently performed with cyclopentadiene (**28**) and α -methylstyrenes **31** as dipolarophiles (Scheme 13).²⁹ Different Binol-derived phosphoric acids (pKa 13-14 in acetonitrile) were initially assayed as organocatalysts giving very low yields. However, the more acidic [H8]-Binol-based *N*-trifluorophosphoramides **33** (pKa 6-7 in acetonitrile) gave pyrazolidines **29** and **32**, respectively, in high yields and enantioselectivities. Cycloadducts **29** were isolated mainly as *cis*-diastereomers, whereas α -methylstyrene adducts **32** were obtained as single diastereomers. The cycloaddition product **29** with R = *t*-Bu was transformed by SmI₂ reduction into a 1,3-diamine with a core structure similar to the influenza drug peramivir.³⁰ By oxidation of cycloadduct **32** (R = *t*-Bu) with copper(II) chloride the corresponding pyrazoline was obtained maintaining the ee value.

However, for the [3+2] cycloaddition of *N*-benzoylhydrazones **20** with ethyl vinyl ether **23** ($R^2 = Et$) the [H8]-Binol derived *N*-triflylphosphoramide **34** was the optimized catalyst. The corresponding *cis*-pyrazolidines **24** ($XR^2 = OEt$) were obtained in good yields and enantioselectivities (Scheme 14).³¹ However, for the cycloaddition with ethyl vinyl thioether **23** ($XR^2 = SEt$) the Spinol-derived *N*-triflylphosphoramide **35** was the best organocatalyst affording pyrazolidines **24** ($XR^2 = SEt$) in good yields, diastereo- and enantioselectivities.

Scheme 14 *N*-Triflylphosphoramides as chiral organocatalysts in the intermolecular 1,3-DC of benzoylhydrazones 20.

The mechanism of *N*-triflylphosphoramide-catalyzed asymmetric [3+2] cycloadditions was explored with DFT (MO6-2X) calculations.³¹ Protonation of hydrazones **20** by these Brønsted acids produces ion-pair complexes, which are more reactive than those formed from azomethine imines by 1,2-prototropy of the hydrazone through the transition state **I** (Scheme 15). These ion-pairs hydrazonium-phosphoramide anions are reactive in $[3^++2]$ cycloadditions and only small distortion³² of them are required in the transition state **II** giving in this case the *cis*-pyrazolidines **24**. The origin of enantioselectivities was also explained.

Scheme 15 Uncatalyzed and catalyzed 1,3-DC of hydrazones and olefins.

2.2 From 1,2-disubstituted hydrazines

The condensation of 1,2-disubstituted hydrazines and *N*-substituted carbazates or hydrazides with carbonyl compounds generates in situ directly the corresponding acyclic azomethine imines,³³ which can be trapped in situ by dipolarophiles through an inter- or intramolecular [3+2] cycloaddition.¹⁰ In this case, they react preferentially with electron-deficient dipolarophiles under thermal conditions.

Intermolecular 1,3-DC of azomethine imines **37**, generated in situ from aldehydes and N^{l} -alkyl- N^{2} -acyl hydrazines **36**, takes place with electron-deficient dipolarophiles under refluxing toluene using a Dean-Stark trap (Scheme 16).³⁴ The corresponding 3,4-disubstituted pyrazolidines **38-40**, derived from benzaldehyde were obtained as a mixture of *cis/trans* diastereomers in low yields.

Scheme 16 Thermal intramolecular 1,3-DC of azomethine imines derived from hydrazine 36.

The first and the only example of an enantiocatalytic three-component 1,3-DC of aldehydes, hydrazides and alkynes was performed using a PyBox 45/Cu(I) complex as catalyst and a chiral binaphthyl dicarboxylic acid 46 as cocatalyst (Scheme 17).³⁵ N^l -Benzylbenzoylhydrazide 41 was used for the generation of the corresponding azomethine imine intermediates 42, which react with terminal alkynes affording pyrazolines 43 in a chemoselective manner (>95:5), only small amounts of compounds 44 resulting from the nucleophilic addition of copper acetylide to 42 were also obtained. Aromatic and aliphatic aldehydes can be used in the presence of 4Å MS to eliminate the water formed during the condensation step. Moreover, aromatic and aliphatic alkynes can be used as well affording the corresponding pyrazolines 43 in high enantioselectivities (Scheme 17).

Scheme 17 Three-component enantiocatalytic 1,3-DC of hydrazide 41 with aldehydes and acetylenes.

A representative 3,4-disubstituted pyrazoline 43a (with $R^1 = R^2 = Ph$) was further transformed into different heterocyclic compounds 47 and 48, as well as the diamine 49 by reduction of the last one with samarium diiodide (Scheme 18).

Scheme 18 Synthetic applications of pyrazoline 43a.

3 Cyclic azomethine imines incorporating C-N in the ring

Several types of heterocyclic systems with C-N double bond incorporated in a ring are a subclass of azomethine imines (Scheme 1).¹⁰ These types of dipoles have been extensively studied allowing the synthesis of different ring-fused pyrazolidines, pyrazolines, and pyrazoles.

3.1 Heterocyclic hydrazones derived azomethine imines

Few examples have been describes using heterocyclic azomethine imines mainly in intramolecular processes. Heterocyclic azomethine imines of the type **51** can be prepared from the corresponding aldehydes **50** bearing a halogen atom at the γ - or δ -position. A cascade cyclization and 1,3-DC gave all-*cis* tricyclic compounds **52** in high yields (Scheme 19).³⁶

Scheme 19 Cascade cyclization and 1,3-DC of hydrazones derived from 50.

Organic & Biomolecular Chemistry

Azomethine imines **54** can be prepared by MW heating of benzoylhydrazides **53** bearing an alkyne in the chain through an intramolecular hydroamination reaction (Scheme 20).³⁷ The reactivity of one example **54a** with methyl acetylenedicarboxylate gave the fused pyrazoline **55** in moderate yield.

Scheme 20 Synthesis of azomethine imines by intramolecular hydroamination.

3.2 Isoquinolinium-N-aryl imides

N-Iminoisoquinolin-2-ium ylides **57** are the most recently used cyclic azomethine imines bearing a C-N bond in the ring.¹⁰ They have been mainly used in metal-catalyzed [3+2] cycloadditions not only with electron-deficient dipolarophiles but also with electron-rich alkenes. In addition, organocatalyzed processes, including asymmetric ones, have also been studied. A direct access to this type of intermediates is the cascade cyclization reaction of the aldehyde **56** with hydrazines to afford azomethine imines **57**,³⁸ which can be trapped in situ with *N*-phenylmaleimide (NPM) (Scheme 21).³⁶ Cycloadducts **58** were obtained as mixture of *endo:exo* diastereomers (2:1-3:1). The reaction of the aldehyde **56** with benzylhydrazine in the presence of dimethyl maleate gave the cycloadduct **59** with all-*cis* relative configuration. The same 3:1 mixture of cycloadducts **60** was obtained by reaction of the aldehyde **56** with hydrazine hydrate in the presence of dimethyl maleate or fumarate. In the case of dimethyl acetylenedicarboxylate a 5:1 mixture of diastereomeric fused pyrazolines **61** were isolated under toluene reflux (Scheme 21).

Scheme 21 Cascade cyclization 1,3-DC of hydrazines derived from 56.

Already prepared C,N-cyclic azomethine imines **57** (with R = Bz) were used for the first time as dipole in enantiocatalyzed [3+2] cycloadditions using enals **62** as dipolarophiles and titanium binolate complexes as catalysts (Scheme 22).³⁸ The 2:1 (*S*)-Binol/Ti(O*i*-Pr)₄ complex gave at 0 °C the corresponding *exo*-cycloadducts **63** in high yields, diastereo-, and enantioselectivities. Structurally related C,N-cyclic azomethine imines **65** were prepared in situ from **64** under basic conditions using 2,6-di-*tert*-butyl-4-methylpyridine (DTMP) as base compatible with the Lewis acid as catalyst. The resulting cycloadducts **66** were obtained mainly as *exo*-adducts with β -substituted enals (**62**, $R^2 = H$), whereas β -unsubstituted enals (**62**, $R^3 = H$) gave mainly *endo*-cycloadducts **67** (Scheme 22).

Scheme 22 Enantiocatalyzed 1,3-DC of C,N-cyclic azomethine imines with enals.

Samarium diiodide-mediated N-N cleavage of the adduct **66a** (with $R^1 = R^2 = H$, $R^3 = Me$) gave the tetrahydroisoquinoline **68** (Scheme 23).³⁸

Scheme 23 Reductive N-N bond cleavage of compound 66a.

The same type of metal-catalyzed 1,3-DC of the azomethine imine **57** with unsaturated nitriles **69** was performed using a dicationic nickel(II) complex containing bis {(R)-1-[(S_P)-2-(diphenylphosphino)ferrocenyl]ethyl}cyclohexylphosphine [(R, S_P)-Pigiphos] **71** as catalyst (Scheme 24).³⁹ The [3+2] cycloaddition gave compounds **70** mainly as the *endo*-diastereomer in good yields and enantioselectivities.

Scheme 24 Ni-Pigiphos-catalyzed 1,3-DC of C,N-cyclic azomethine imines 57 with unsaturated nitriles.

Asymmetric inverse-electron-demand 1,3-DC of C,N-cyclic azomethine imines 57 with *tert*butyl vinyl ether could be performed firstly with the chiral dicarboxylic acid 74 as Brøsted acid (Scheme 25).⁴⁰ The corresponding adducts 72 were obtained with different regioselectivity by interaction of the LUMO of the dipole with the HOMO of the alkene. Moreover, *exo*-cycloadducts 72 were obtained in high yields and enantioselectivities. Vinilogous aza-enamines gave mainly *exo*cycloadducts 73 in high yields and good enantioselectivities. The hydrazone unit of compound 73 (with $R^1 = Br$, $R^2 = H$) was transformed into the corresponding cyano group by magnesium monoperoxyphthalate in 80% yield.

Scheme 25 Organocatalyzed asymmetric 1,3-DC of cyclic azomethine imine 57 with electron-rich alkenes.

The thermal [3+2] cycloaddition reaction of azomethine imines **57** with α -substituted allenoates **75** occurs under mild reaction conditions to provide adducts **76** as a mixture of diastereomers in high regioselective manner (Scheme 26).⁴¹ The major *endo*-diastereomer could be separated and isolated by flash chromatography or by recrystallization. In the case of γ -substituted allenoates **77** the 1,3-DC takes place in lower yields giving mainly *exo*-cycloadducts **78**.

Scheme 26 Thermal [3+2] cycloaddition of azomethine imines 57 with allenoates.

When the same 1,3-DC was carried out in the presence of a trialkyl phosphine as catalyst (20 mol%) two different reaction pathways, [3+2] and [4+3] cyclizations depending on the phosphine and the allenoate were observed. In the case of α -alkyl substituted allenoates only [3+2] cycloaddition products **79** were obtained independently of the phosphine used (Scheme 27).⁴² However, α -benzyl substituted allenoates gave mainly the diazepine derivatives **80** through a [4+3] cycloaddition.

Scheme 27 Phosphine-catalyzed [3+2] versus [4+3] cycloadditions of azomethine imines 57 with allenoates 75.

However, when γ -substituted allenoates 77 are used as dipolarophiles the phosphinecatalyzed 1,3-DC with azomethine imines **57** gave the [3+2] cycloaddition. This process has been carried out with the ferrocenyl diphosphine **82** as chiral catalyst affording tetrahydroisoquinoline derivatives **81** in good yields, high *exo*-diastereoselectivities and moderate to high enantioselectivities (Scheme 28).⁴³

Scheme 28 Enantiocatalyzed [3+2] cycloaddition of azomethine imines 57 with γ -substituted allenoates 77 by the chiral phosphine 82.

Based on previous experiments about the formation of phosphonium-inner salts by reaction of allenoates with phosphines,⁴⁴⁻⁴⁶ the zwiterionic intermediates **83** and **84** were proposed. Intermediate **84** underwent δ -addition to the azomethine imine **57** to give **85** (Scheme 29).⁴³ Intramolecular Michael addition gave **86**, which after [1,2] proton transfer afforded intermediate **87**. Final elimination of the phosphine catalyst yielded the cycloadduct **81**.

Scheme 29 Mechanism of the phosphine-catalyzed [3+2] cycloaddition of 57 with 77.

Triflyl alkynes **88** gave 1,3-DC by reaction with azomethine imines **57** at room temperature, and after oxidative aromatization, pyrazoleisoquinoline triflones **89** were regioselectively obtained (Scheme 30).⁴⁷

Organic & Biomolecular Chemistry

Scheme 30 [3+2] Cycloaddition of 57 with triflyl alkynes 88.

A [4+3] cycloaddition has been observed when 1,2-diaza-1,3-dienes **91**, generated in situ from the corresponding α -halo hydrazones **90**, are allowed to react with C,N-cyclic azomethine imines **57** (Scheme 31).⁴⁸ These 1,2-diaza-1,3-dienes **91** behave differently than azaenamines, which gave [3+2] cycloaddition with **57** (Scheme 25).⁴⁰ In this case, an unprecedent [4+3] cycloaddition afforded highly functionalized 1,2,4,5-tetrazepine derivatives **92**, which were obtained under mild reaction conditions.

Scheme 31 [4+3] Cycloaddition of azomethine imines 57 with diazadienes 91.

In the case of isocyanides **93** these azomethine imines **57** experimented a [5+1] cycloaddition at room temperature leading to the corresponding imino-1,3,4-oxadiazin-6-one derivatives **94** in high yields (Scheme 32).⁴⁹ Related C,N-cyclic azomethine imine **64** not fused to the aromatic ring also gave this [5+1] cycloaddition with *tert*-butyl isocyanide in the presence of DTBMP as a base affording product **95** (Scheme 32).⁴⁹

Organic & Biomolecular Chemistry Accepted Manuscrip

Scheme 32 [5+1] Cycloaddition of compounds 57 with isocyanides.

Amine-catalyzed enantioselective [3+2] cycloadditions of aldehydes with azomethine imines **57** lead to the formation of adducts **97** (Scheme 33).⁵⁰ Intermediate enamines formed with the chiral prolinol silyl ether **99** gave intermediate products **96**, which after water attack afforded compounds **97**. These hemiaminals were reduced in situ with sodium borohydride to 1-substituted tetrahydroisoquinolines **98** in high diastereo- and enantioselectivities.

Scheme 33 [3+2] Cycloaddition of azomethine imines 57 and aldehydes organocatalyzed by the chiral silylated prolinol 99.

The same group performed an enantioselective 1,3-DC using an intermediate dienamine **57** and enals ($R^2 = aryl$), and a silylated prolinol **102** as organocatalyst. By subsequent reduction of the aldehyde functionality the corresponding alcohols **100** were isolated in good yields, diastereo- and enantioselectivities (Scheme 34).⁵¹ However, when aliphatic enals ($R^2 = alkyl$) were used, regioisomeric derivatives **101** were obtained according to the formation of α,β -unsaturated iminium ion as intermediates. Similar iminium-dienamine reactivity has been reported independently with prolinols **99** and **102** by Alemán and Fraile.⁵²

Scheme 34 [3+2] Cycloaddition of compound 57 with enals organocatalyzed by the chiral silylated prolinol 102.

A new type of 1,3-DC has been recently performed with azomethine imines **57** and *N*-acyliminium ions **105** affording cycloadducts **103** (Scheme 35).⁵³ The chiral Lewis base **104** acted as organocatalyst forming the corresponding activated intermediates **105** by reaction with mixed anhydrides.

Scheme 35 1,3-DC of compounds 57 with mixed anhydrides catalyzed by a chiral Lewis base 104.

Another family of isoquinolinium ylides are the corresponding unsaturated systems which should be prepared in situ in a two- or three-component reactions. Thus, *N*'-(2- alkynylbenzylidene)hydrazides **106** react with bromine and α,β -unsaturated ketones via a three-component reaction to afford either 6-bromo-4*H*-pyrazolo[5,1-*a*]isoquinolines **108** in NMP at 70 °C in the presence of DABCO as base, or 6-bromo-1,2,3-10b-tetrahydropyrazolo[5,1-*a*]isoquinolines **109** in DMAc at room temperature in the presence of potassium phosphate as base (Scheme 36).⁵⁴ These processes took place by a bromine-promoted 6-*endo*-cyclization to give the isoquinolinium-2-yl amide **107** followed by a [3+2] cycloaddition with the α,β -unsaturated carbonyl compound followed by aromatization. The same group has shown that *H*-pyrazolo[5,1-*a*]isoquinolines present promising activity as protein tyrosine phosphatase inhibitor.

Scheme 36 Three-component reaction of hydrazides 106 with bromine and enones.

When the former process was carried out with 2-alkynyl benzaldehydes **110**, ptoluenesulfonyl hydrazide and unsaturated carbonyl compounds in the presence of bromine or iodine, the multicomponent reaction afforded isoquinolines **108** with alkyl groups at the 1 and 5 positons.⁵⁵ A similar process has been performed using AgOTf as catalyst, which after a 6-*endo-dig* cyclization produced the isoquinolinium-2-yl imide **111**. The three-component reaction between 2alkynyl benzaldehydes **110**, tosyl hydrazide and α,β -unsaturated carbonyl compounds gave functionalized *H*-pyrazolo[5,1-*a*]isoquinoline-1-carboxylates **112** (Scheme 37).⁵⁶

112 (50-90%)

Scheme 37 Silver triflate-catalyzed three-component reaction of 2-alkynyl benzaldehydes 110, tosyl hydrazide and α,β -unsaturated esters.

When an acetylenic dipolarophile is used, only a halogen or silver triflate promotes the [3+2] cycloaddition. Thus, *N*²-(2-alkynylbenzylidene)hydrazides **106** react with acetylenes either catalyzed by silver triflate or promoted by bromine or iodine in the presence of NaOAc. In the case of dimethyl acetylenedicarboxylate (DMAD) either in the presence of AgOTf or bromine the fused dihydroisoquinolines undergo a rearrangement involving a N-N homolysis to give compounds **113** or **114**, respectively (Scheme 38).⁵⁷ However, in the presence of iodine the fused 1,2-dihydroisoquinolines **115** are obtained.

Scheme 38 Reaction of hydrazones 106 with dimethyl acetylenedicarboxylate.

The same process in the presence of terminal acetylenes gave the *H*-pyrazolo[5,1*a*]isoquinolines **116** (X = H)^{58a} in the case of AgOTf or **116** (X = Br, I)^{58b} first by a bromine or iodine promoted cyclization followed by a silver-catalyzed nucleophilic addition of the acetylide to give the isoquinolinium-2-yl imide of the type **117** (Scheme 39). However, when this process is carried out in the presence of tosyl azide with silver triflate and copper(I) bromide, as cocatalyst, 5sulfonylamine-substituted isoquinolines **117** were obtained (Scheme 39).⁵⁹

Scheme 39 Reaction of hydrazides 106 with alkynes.

N-Allyl ynamides reacted with N'-(2-alkynylbenzylidene)hydrazides 106 in a process catalyzed by silver triflate and palladium acetate generating 2-amino-H-pyrazolo[5,1*a*]isoquinolines **118** in good yields (Scheme 40).⁶⁰ In this case, the [3+2] cycloaddition takes place, after the silver-promoted cyclization to give azomethine imines 111, with vnamido-palladium π allyl complexes 119 affording intermediates 120. Subsequently, an intramolecular [3,3]-sigmatropic rearrangement produces compound **121**, which undergoes aromatization releasing a tosyl group. 120

An alternative route to pyrazoloisoquinolines 116 (X = H) used brooalkynes as dipolarophiles. In this case, the alkynylation of **111**, formed by the silver-catalyzed cyclization of 106, takes place by a C-H activation. The bromoalkyne is activated via oxidative addition to CuI, which through a concerted metallation-deprotonation process would give intermediates 122. After reductive elimination, intermediates 123 undergo a 5-endo-dig-cyclization to give 124, followed by subsequent aromatization to form the final *H*-pyrazolo[5,1-*a*]isoquinolines **116** (Scheme 41).⁶¹

Organic & Biomolecular Chemistry

Alternatively, by using primary alcohols and hydrazides **106** instead of aldehydes **110**, the presence of the Dess-Martin reagent (DMP) as oxidant is compulsory to afford 6-monosubstituted *H*-pyrazolo[5,1-a]isoquinolines **135** (Scheme 50).^{70a,b}

Scheme 50 Tandem reaction of hydrazides 106 with alcohols.

The same transformation can be performed by a silver triflate-palladium chloride cooperative catalysis. The presence of oxygen promotes the palladium-catalyzed oxidation of the alcohol to the corresponding aldehyde or ketone. The in situ generated enolate attacks the isoquinolinium-2-yl imide followed by condensation and aromatization to afford products **135** in 47-90% yield.^{70c}

Silver triflate-copper(II) acetate cooperative catalysis has been used for the cyclization/[3+2] cycloaddition of *N*'-(2-alkynylbenzylidene) hydrazides **106** with allenoates **77** in the presence of dioxygen to afford *H*-pyrazolo[5,1-*a*]isoquinolines **136** (Scheme 51).^{71a} The proposed mechanism involves a peroxy-copper(III) intermediate **138**, which evolves to **139** and, after elimination of Cu(II)-OH generates a carbonyl compound **140**. Final aromatization yielded products **136** in moderate to good yields. When this reaction was performed with Ph₃P as catalyst the corresponding isoquinolines **136** were obtained with a R³CH₂ group instead of the ketone functionality.^{71b}

Scheme 51 Reaction of hydrazides 106 with allenoates 77 in the presence of dioxygen cocatalyzed by silver triflate and copper(II) acetate.

Silver-rhodium(I) cooperative catalysis has been used for the reaction of hydrazides **106** with cycloprop-2-ene-1,1-dicarboxylate⁷² or with 2-vinyloxirane⁷³ for the synthesis of the corresponding *H*-pyrazolo[5,1-*a*]isoquinolines **141** or **142**, respectively (Scheme 52). The use of the Wilkinson catalyst is crucial for the [3+2] cycloaddition.

Scheme 52 Silver-rhodium(I) cooperative catalysis in the reaction of 106 with cycloprop-ene-1,1dicarboxylate or 2-vinyloxirane.

When silver triflate and copper(II) chloride are used as cooperative catalysts it is possible to prepare *H*-pyrazole[5,1-*a*]isoquinolines **135** through a three-component process. Thus, 2-alkynyl benzaldehydes, tosyl hydrazide and tertiary amines in air gave products **135** by a silver-catalyzed cyclization and copper(II)-catalyzed oxidation of an aliphatic C-H bond of the tertiary amine in air (Scheme 53).⁷⁴ A related process using palladium dibromide as cocatalyst gave isoquinolines **131**, which has been performed starting from the hydrazides **106** instead of aldehydes **110** (Scheme 53).^{75a} The same transformation has been previously performed using Fe₂(CO)₉ as cocatalyst (5 mol%) and *tert*-butyl hydroperoxide (3 equiv) affording products **135** in 46-83% yields.^{75b}

Methylene indolinones have been used as dipolarophiles for the diastereoselective construction of fused *H*-pyrazolo[3,2-*a*]isoquinolines **143** as a mixture of diastereomers (Scheme 54).⁷⁶ In this case, the Wu *et al.*⁵⁶ methodology was applied to a process starting from *N'*-(alkylnylbenzylidene) hydrazides **106** under silver-catalyzed 6-*endo* cyclization to generate the *N*-iminoisoquinolinium ylide **111**.

Scheme 54 Preparation of fused spirooxindoles 143.

In general, these unsaturated isoquinolinium imideshave been mainly used in [3+2] cycloaddition with acetylenic dipolarophiles. The only example of a [3+3] cycloaddition of azomethine imines **144** has been described using cyclopropane diesters and a Ni(ClO₄)₂ complex with a trisoxazoline derivatives **146** as chiral ligand.⁷⁷ This process allows the preparation of 6,6,6-tricyclic dihydroisoquinoline derivatives **145**, in general with high diastereo- and enantioselectivities (Scheme 55). This reaction is based on the non-asymmetric example described previously by Charette *et al.*⁷⁸ with *N*-benzoyliminoisoquinolinium ylide and methyl 2-phenylcyclopropane-1,1-dicarboxylate catalyzed by Ni(ClO₄)₂ in modest yield (21%).

Scheme 55 Enantiocatalyzed [3+3] cycloaddition of azomethine imines 144 and cyclopropane diesters.

3.3 Pyridinium- and quinolinium imides

Pyridinium imides **147**, also called *N*-iminopyridinium ylides or pyridin-*N*-imines, are masked cyclic azomethine imines incorporating C-N in the ring, which react mainly with acetylenic dipolarophiles.¹⁰ They are unstable and have to be generated in situ from *N*-aminopyridinium halides and since the aromaticity of pyridine is broken after the cycloaddition, they have to be oxidized to give the desired product. A greater stability can be achieved by introducing an electron-withdrawing group such as acyl, alkoxycarbonyl, or sulfonyl to afford ylides **148**. *N*-Benzoyliminopyridinium ylides **150** have been the most used imines of this family. They can be prepared by benzoylation of the corresponding *N*-aminopyridinium salts **149** (Scheme 56) easily accessible by direct *N*-amination of pyridine using hydroxylamine-*O*-sulfonic acid.⁷⁹⁻⁸¹ Alternatively, *N*-aminopyridinium salts **147** can be prepared using different electrophilic amination reagents, especially efficient being *O*-(2,4-dinitrophenyl) hydroxylamine, which gave good yields with several types of substituted pyridines, quinolines and isoquinolines.⁸²

Scheme 56 Synthesis of *N*-benzoyliminopyridinium ylides 150.

By using alkynes as dipolarophiles pyrazolopyridines can be prepared⁸³ which exhibit a wide range of biological activities including dopamine D3 receptor antagonist and partial agonist,⁸⁴ dopamine D4 antagonist,⁸⁵ as well as adenosine A1 receptor antagonist,⁸⁶ and antiherpetic⁸⁷ and antiallergenic⁸⁸ properties. Consequently, they are applicable in the treatment of neurological disorders such as schizophrenia, attention-deficit disorder, and Parkinson's disease.

Polystyrene-bound alkenes **152** have been used for the solid-phase synthesis of pyrazolopyridines **153** by in situ generation of pyridinium imides **147** from *N*-aminopyridinium salts **151** followed by TFA cleavage (Scheme 57). Alternatively, by using NaOMe in THF/MeOH the corresponding methyl esters can be isolated.⁸⁹

Scheme 57 Solid-phase synthesis of pyrazolopyridines 153 by a [3+2] cycloaddition of pyridinium imides with polymer-bound propiolates 152.

In the case of using arynes as dipolarophiles and pyridinium imides **148** with different electron-withdrawing groups on the imide nitrogen, it was found that the pyrido[1,2-b] indazoles **155** are obtained in high yields (Scheme 58) using the tosyl derivatives **154**, whereas the benzoyl, pivaloyl, benzyloxycarbonyl, and *tert*-butyloxycarbonyl ones gave lower results.⁹⁰ This methodology has been also used with *N*-tosylisoquinolinium imides to afford indazolo[3,2-*a*] isoquinolines.

Scheme 58 Synthesis of pyrido[1,2-*b*]indazoles 155 by aryne [3+2] cycloaddition with *N*-tosyl pyridinium imides.

The thermal [3+2] cycloaddition of *N*-benzoylquinolinium imide **156** with allenoates **75** provides products **157** in good yields, albeit with poor diastereoselectivity (Scheme 59).⁹¹ This cycloaddition has been carried out with *N*-benzoylisoquinolinium imides with similar results, concerning yield and diastereoselectivity.

Scheme 59 Thermal [3+2] cycloaddition of *N*-benzoylquinolinium imide 156 with allenoates.

A formal [3+2] cycloaddition catalyzed by a gold complex **159** between *N*-benzoyliminopyridinium ylides **158** and *N*-alkynylsulfonamides gave 2,4,5-trisubstituted oxazoles **160** in high yields (Scheme 60).⁹²

Scheme 60 Gold-catalyzed formal [3+2] cycloaddition of *N*-benzoyliminopyridinium ylides 158 with *N*-alkynyl sulfonamides.

The benzocondensed azomethine imines **156** have been employed in [3+3] cycloadditions. Thus, the nickel-catalyzed [3+3] cycloaddition of *N*-benzoylquinolinium imide **156** with 1,1-cyclopropane diesters provided products **161** in modest to good yields and moderate diastereoselectivity (Scheme 61).⁷⁸ This cycloaddition has been also performed with the *N*-benzoylisoquinolinium ylide with modest yield (21%).

Scheme 61 Ni-catalyzed formal [3+3] cycloaddition of quinolinium imides and 1,1-cyclopropane diesters.

An enantioselective formal [3+3] cycloaddition has been performed also with *N*-benzoylpyridinium ylides **158** and silylated enol diazoacetates **162** using the rhodium catalysts **164**. Bicyclic dearomatized 1,2,3,6-tetrahydropyridazine derivatives **163** were obtained in high yields and enantioselectivities (Scheme 62).⁹³ The reaction is triggered by Rh(II)-catalyzed dinitrogen extrusion with formation of a rhodium carbenoid intermediate followed by addition of the pyridinium ylide.

164: R = *t*-Bu, Bn

4 Cyclic azomethine imines incorporating a N-N bond in a ring

The most studied cyclic azomethine imines incorporating a N-N bond in a ring are *N*-alkylidene-3-oxopyrazolidinium imides **166**, which are stable and readily accessible. They have been employed as 1,3-dipoles in thermal and metallo- or organo-catalyzed cycloadditions not only [3+2] but also [3+3], [4+3] and [3+2+3] ones. These annulations reactions gave rise to dinitrogen-fused heterocycles including tetrahydropyrazolo-pyrazolones, -pyridazinones, -diazepinones, and – diazocinones, which are important products or intermediates for the preparation of useful chemicals and diverse bioactive molecules.

4.1 N-Alkylidene-3-oxopyrazolidin-1-ium-2-ides

Azomethine imines **166**, derived from pyrazolidin-3-ones **165**, are usually prepared by condensation with carbonyl compounds.¹⁰ They can be isolated, especially in the case of aromatic aldehydes, by heating in anhydrous methanol catalyzed by means of trifluoroacetic acid (Scheme 63).^{10,94}

Scheme 63 Synthesis of azomethine imines 166 from pyrazolidin-3-ones 165.

A recent new route to azomethine imines has been described using hydrazones derived from ketones and *N*-alkoxycarbonylhydrazines **167** and alkenes (Scheme 64).⁹⁵ Under microwave assisted heating at 150 °C the intermediate isocyanate is formed and through a concerted alkene aminocarbonylation pathway the corresponding azomethine imines **168** are produced in good yields. Several type of acyclic and cyclic alkenes can be used including vinyl ethers and enamides. With terminal alkenes ($\mathbb{R}^4 = \mathbb{H}$) a total regioselectivity was observed.

Scheme 64 Synthesis of azomethine imines 168 from hydrazones 167 and alkenes.

4.1.1 Thermal cycloadditions

A common reaction of azomethine imines **169** with dipolarophiles such as methyl propiolate or dimethyl acetylenedicarboxylate gave the corresponding cycloadducts 2,3-dihydro-1*H*,5*H*-pyrazolo[1,2-*a*]pyrazol-1-ones **170** (Scheme 65).⁹⁴

Scheme 65 [3+2] Cycloaddition of azomethine imines 169 with alkynes.

Stereoselective synthesis of fused pyrazolones have been studied with racemic pyrazolidin-3-one **171**, which after reaction with benzaldehydes and followed by [3+2] cycloadditions of the generated azomethine imines **172** with electron-deficient dipolarophiles such as methyl acrylate, dimethyl acetylene dicarboxylate and dimethyl maleate, pyrazolopyrazolone derivatives **173-175** were obtained with high stereocontrol (Scheme 66).^{96,97} The stereoselective cycloaddition of azomethine imines **172** with maleimides provided cycloadducts **176** when the aldehydes has not substituents at the *ortho*-position. However, with *ortho*-substituted aldehydes diastereomeric adducts **177** were formed.^{98,99} Similarly, butyraldehyde and acetone react with pyrazolidinone **171** under acid-catalyzed process to afford the corresponding azomethine imines, which react under thermal conditions with dimethyl acetylenedicarboxylate, methyl acrylate, methyl maleate or fumarate and *N*-phenylmaleimide to give the corresponding cycloadducts.¹⁰⁰

Scheme 66 Diastereoselective [3+2] cycloaddition of azomethine imines 172 with dipolarophiles.

In the case of the Cu(I)-catalyzed [3+2] cycloaddition of azomethine imines 172 (Ar = Ph) it takes place at room temperature in acetonitrile using the Hünig's base with methyl propiolate giving the product 178 (Scheme 67).¹⁰¹ When the chiral ynone 179 was allowed to react with 172 a mixture of diastereomeric cycloadducts 180 was obtained.

Organic & Biomolecular Chemistry Accepted Manuscrip

Scheme 67 Diastereoselective Cu(I)-catalyzed [3+2] cycloaddition of azomethine imine 172 with acetylenic dipolarophiles.

Azomethine imines **166** and **172** derived from unsubstituted **165** and substituted **171** pyrazolidin-3-ones, respectively, have been used as dipoles in the reaction with α - (trifluoromethyl)acrylates affording the corresponding adducts with moderate diastereoselectivity.¹⁰² In the case of alkynyl Fischer carbene complexes a regioselective [3+2] cycloaddition takes place giving, after oxidative demetallation, the corresponding functionalized pyrazolopyrazolone derivatives **182** (Scheme 68).¹⁰³

Scheme 68 [3+2] Cycloaddition of azomethine imines 166 with alkynyl Fischer carbene complexes.

Organic & Biomolecular Chemistry

Several pyrazolidin-3-ones bearing a chiral chain have been applied as precursors of chiral azomethine imines in diastereoselective [3+3] cycloadditions. Thus, 5-substituted pyrazolidin-3-ones **183** derived from 2,3-unsaturated sugar 1,5-lactones, react at room temperature with acetone and then with dimethyl acetylenedicarboxylate (DMAD) to provide either the cycloadduct **184** or with two equivalents of DMAD, under camphorsulfonic acid (CSA) catalysis, to give mainly the cycloadduct **185** (Scheme 69).¹⁰⁴

Scheme 69 Diastereoselective [3+2] cycloaddition of 183 with DMAD.

The intramolecular [3+2] cycloaddition of azomethine imine **187** derived from pyrazolidin-3-one **165** ($R^1 = R^2 = R^3 = R^4 = H$) and the glucose-derived aldehyde **186**, gave the diazatriquinane **188** (Scheme 70).¹⁰⁵ This methodology has been studied with different sugar-derived hexen-5-als giving the corresponding diazatriquinanes in high yields and total stereocontrol, which were used for biological screening.

Different type of dipolarophiles have been investigated under thermal conditions with azomethine imines **166** derived from unsubstituted **165**, among them, acetylenic sulfones,¹⁰⁶ arynes,¹⁰⁷ β -nitrostyrenes,¹⁰⁸ cyclic vinyl sulfones,¹⁰⁹ and trifluoroethylidene malonates.¹¹⁰ In the case of using azlactones **189** as dipolarophiles, a [3+2] cycloaddition, followed by a rearrangement at room temperature, gave the pyrazolopirazolone derivatives **190** (Scheme 71).¹¹¹ The cycloadduct intermediates **191** are unstable and rearranged giving **190** with high diastereoselectivity (>20:1).

4.1.2 Copper-catalyzed cycloadditions

In 2003 Fu *et al.* described for the first time that CuI (5 mol%) catalyzed the cycloaddition of the azomethine imine **166** ($R^1 = Ph$) with ethyl acrylate at room temperature in the presence of 0.5 equivalents of Cy₂NMe in dichloromethane giving regioselectively the corresponding cycloadduct in 88% yield. After establishing these reaction conditions, different chiral ligands were assayed, the phosphaferrocene oxazoline **193** giving the highest enantioselectivity for cycloadducts **192** in the reaction with terminal alkynes (Scheme 72).¹¹² The same reaction conditions have been applied to the kinetic resolution of racemic substituted azomethine imines **166** (Scheme 73).¹¹³

Scheme 72 Enantioselective copper-catalyzed [3+2] cycloaddition of azomethine imines ylides 166 with terminal alkynes.

Scheme 73 Kinetic resolution of azomethine imines via a copper-catalyzed [3+2] cycloaddition.

The [3+2] cycloaddition of azomethine imines **169** with the *N*-acryloylpyrazolidinone **194** catalyzed by the chiral complex $Cu(OTf)_2$ ·bisoxazoline **196** gave regio- and diasteroselectively *exo*-cycloadducts **195** in good yields (Scheme 74).¹¹⁴ These processes have been performed only with this pyrazolidinone **194** able to be chelate by the copper complex and different C5-substituted azomethine imines.

The chiral bis(imidazolidine) **198** CuOAc complex has been used as catalyst for the [3+2] cycloaddition of the azomethine imine **169** with propiolates affording cycloadducts **197** with modest enantioselectivities (Scheme 75).¹¹⁵

Scheme 75 Enantioselective copper-catalyzed [3+2] cycloaddition of azomethine imines 169 with propiolates using ligand 198.

The same group developed a better ligand PyBodine (L-Ala) **199** able to perform this cycloaddition with $Cu(OAc)_2$ as metallic salt in better yields and enantioselectivities (Scheme 76).¹¹⁶

Scheme 76 Enantioselective copper-catalyzed [3+2] cycloaddition of 169 with propiolates using ligand 199.

Group 11 metal amides, copper(I) and silver bis(trimethylsilyl)amides (HMDS) in THF catalyzed the same [3+2] cycloaddition of **166** with terminal alkynes with opposite regioselectivity. This process has been performed in an enantioselective manner when (*S*)-DIP-BINAP ligand **201** was used with CuHMDS. Thus, the corresponding 5,7-disubstituted cycloadducts **200** were obtained in good yields and enantioselectivities (Scheme 77).^{117,118} This regioselectivity is explained by 1,2-addition of the copper acetylide to the iminium moiety followed by intramolecular cyclization.

201: Ar = 3,5-*i*-Pr₂C₆H₃

Scheme 77 Enantioselective copper-catalyzed [3+2] cycloaddition of azomethine imines 166 with terminal alkynes.

By using propiolylpyrazoles **202** as acetylenic dipolarophiles terminal and internal alkynes gave very good enantioselection in the [3+2] cycloaddition of azomethine imines **166** catalyzed by a chiral π -cation catalyst **204** (Scheme 78).¹¹⁹ The main difference in this type of copper catalyst

compared to the previous ones is that the copper(I) acetylide-mediated cycloaddition of azomethine imines with terminal alkynes is not operating (Method A). Instead, a Lewis acid-catalyzed cycloaddition by coordination with the carbonyl group (Method B) takes place (Scheme 79).

Scheme 78 Enantioselective copper-catalyzed [3+2] cycloaddition of 166 with propiolylpyrazoles catalyzed by the chiral complex 202.

Scheme 79 Strategies for the copper-catalyzed [3+2] cycloaddition of azomethine imines 166 with alkynes.

The racemic copper-catalyzed [3+2] cycloaddition has been performed not only with CuI but also with Cu(I) zeolites as the heterogeneous ligand-free catalysts.^{120,121} They are easy to be removed by simple filtration and can be recycled up to six times without decreasing efficiency. Heterogeneous supported copper hydroxide Cu(OH)_x/Al₂O₃ has been used also as an efficient reusable catalyst.¹²²

Organic & Biomolecular Chemistry

The catalytic asymmetric cross-1,3-DC of two different dipoles, azomethine ylides, generated from iminoesters **205** and imines **166**, gave highly substitutd 1,2,4-triazinanes with total diastereo- and enantioselectivity. (*S*, *S*_P)-*t*-Bu-Phosferrox **207** as ligand and AgOAc or Cu(MeCN)BF₄ salts have been assayed as chiral catalysts for this [3+3] cycloaddition. The best results were obtained with the Cu complex giving the cycloadducts **206** in high yields, diastereo-(>20:1) and enantioselectivities (Scheme 80).¹²³

207: $R^1 = t$ -Bu, $R^2 = 3,5$ -(F_3C)₂ C_6H_3

Independently, a similar [3+3] cycloaddition has been performed using the ferrocenyl P,Nchiral ligand **208** and Cu(MeCN)₄ClO₄ salt as catalyst. This process takes place giving products **206** with good yields (71-89%), diastereo- (>20:1) and enantioselectivities (50-96%).¹²⁴

Isocyanides **209** and azomethine imines **169** gave a [3+3] cycloaddition to give pyrazole[1,2-*a*]triazin-8(4*H*)-ones **210** (Scheme 81).¹²⁵ The process takes place with high stereocontrol using CuI as catalyst and DBU as base at room temperature. Silver salts and other copper salts provided lower yield than CuI. The proposed mechanism involves the formation of the α -cuprioisocyanide followed by nucleophilic addition to the imine and final insertion of the isonitrile **211** into the N-Cu bond to give the imidoyl-copper intermediate **212** and final protonation.

Scheme 81 [3+3] Cycloaddition of azomethine imines 169 and isocyanides 209 catalyzed by CuI.

4.1.3 Other metal-catalyzed cycloadditions

Enantioselective nickel-catalyzed 1,3-DC between azomethine imines **169** and 3-acryloyl-2-oxazolidinone **213** takes place using (*R*)-binaphthyldiimine **215** as chiral ligand to provide cycloadducts *trans*- and *cis*-**214** (Scheme 82).¹²⁶ The process gave mainly the *trans*-diastereomers with a high level of enantioinduction acting the metal complex as chiral Lewis acid coordinating the Ni(II) atom the acryloyloxazolinone. A dipole-HOMO/dipolarophiles-LUMO controlled asymmetric 1,3-DC is proposed.

Scheme 82 Enantioselective Ni(II)-catalyzed [3+2] cycloaddition of azomethine imines 169 and 3acryloyl-2-oxazolidinone 213.

Recently, a Ni(II)-catalyzed enantioselective [3+2] cycloaddition of azomethine imine **166** and alkylidene malonates as dipolarophiles has been described. In this case *trans*-pyrazolone derivatives **216** have been obtained with total diastereoselectivity and good enantioselectivities by using a chiral *N*,*N*'-dioxide **217** as chiral ligand (Scheme 83).¹²⁷ The reaction also proceeds by a dipole-HOMO/dipolarophiles-LUMO interaction, the Ni-complex acting as chiral Lewis acid coordinating the two carbonyl groups of the alkylidene malonate.

Scheme 83 Enantioselective Ni(II)-catalyzed [3+2] cycloaddition of the azomethine imine 166 and alkylidene malonates.

The palladium-catalyzed [3+3] cycloaddition of trimethylenemethane (TMM) with azomethine imines **166** led to the formation of six-membered cycloadducts **219**.¹²⁸ Starting from [2-(acetoxymethyl)-2-propenyl]trimethylsilane **218**, the Pd-TMM complex reported by Trost,¹²⁹ generated from Pd(PPh₃)₄ in DCM gave the best results (Scheme 84). Azomethine imines bearing substituents on the pyrazolidinone ring can also be used in this [3+3] cycloaddition giving the hexahydropyridazines with high diastereoselectivity. However, using substituted TMM different products are formed.

Scheme 84 Palladium-catalyzed [3+3] cycloaddition of trimethylenemethane with the azomethine imines 166.

Gold-catalyzed [3+3] cycloadditions of azomethine imines **166** and propargyl esters have been observed to proceed by a stepwise mechanism with a gold(III) carbenoid **221** as intermediate. The reaction takes place in the presence of 5 mol% of picolinate-gold dichloride (**159**) as catalysts affording adducts **220** with moderate to high diastereoselectivity (Scheme 85).¹³⁰

Scheme 85 Gold(III)-catalyzed [3+3] cycloaddition of azomethine imines 166 with propargyl esters.

Organic & Biomolecular Chemistry

N-Allenyl amides **222** underwent 1,3-DC of azomethine imines **166** under gold(I) catalysis to provide [3+2] cycloadducts **223** (Scheme 86).¹³¹ This process can occur through a gold allene intermediate, which can give another intermediate **224** by an outer-sphere nucleophilic addition. Subsequent intramolecular cycloaddition of **224** yielded the iminium intermediate **225**, which after deauration, gave the final cycloadduct **226**.

Scheme 86 Gold(I)-catalyzed [3+2] cycloaddition of 166 with *N*-allenyl amides 222.

The asymmetric 1,3-DC of azomethine imines **166** to allyl alcohol was possible using stoichiometric amount of a strong Lewis acid formed by diisopropyl (R,R)-tartrate (DIPT) and an being an excess (3 equiv) of butylmagnesium bromide necessary for the deprotonation of allyl alcohol to form the intermediate **228**. The reaction proceeds at 80 °C in acetonitrile affording only the corresponding *trans*-pyrazolinonepyrazolidines **227** (Scheme 87).^{132,133}

Scheme 88 Enantioselective [3+2] cvcloaddition of azomethine imines 166 and homoallyl alcohol catalyzed by magnesium diisopropyl tartrate.

Doyle *et al.* have studied enol diazoacetate 162 as dipolarophile for the [3+2] cycloaddition with azomethine imines 166 catalyzed by $Sc(OTf)_3$ or $In(OTf)_3$ as Lewis acids.¹³⁶ The corresponding cycloadducts 232 are obtained diastereoselectively in good yields. Selective 1,2- $C \rightarrow C$ and $N \rightarrow C$ migrations catalyzed by rhodium(II) salts or CuPF₆ were observed to give six membered rings. However, using rhodium(II) acetate the corresponding [3+3] annulations products

Organic & Biomolecular Chemistry Accepted Manuscript

cis-231 were regio- and diastereoselectively obtained (Scheme 89).¹³⁷ The azomethine imine attacks the vinylogous position of the Rh(II)-vinyl carbine 232 to give the intermediate 233, which after subsequent ring formation followed by extrusion of the catalyst gives the fused bicyclic pyrazolidinones 231.

Scheme 89 Rh-catalyzed [3+3] cyclization of enol diazoacetate 162 with azomethine imines 166.

When a diazoketone **234** was used as dipolarophile a formal [3+2+1] annulation with azomethine imines **166** was observed (Scheme 90).¹³⁸ In this case, a similar intermediate metal carbine **232** (Scheme 89) is trapped by another molecule of the diazoketone **234** to give diastereoselectively products **235** by means of the chiral dirhodium(II) carboxamidate **236**.

Scheme 90 Rh(II)-catalyzed formal [3+2+1] annulations of azomethine imines 166 and diazoketone 234.

4.1.4 Metal-free-catalyzed cycloadditions

Different types of Lewis bases such as amines, phosphines and Lewis and Brønsted acids have been used for the racemic and enantioselective 1,3-DC of azomethine imines with dipolarophiles.

For electron-rich alkenes, such as vinyl ethers **23**, highly reactive nitrosonium hexafluorophosphate must be used as catalyst for the [3+2] cycloaddition of azomethine imines **166** (Scheme 91). The corresponding fused pyridazinones **237** were obtained with low to good *cis/trans* diastereoselectivity.¹³⁹

Scheme 91 NO cation-catalyzed [3+2] cycloaddition of azomethine imines 166 with vinyl ethers.

The first organocatalyzed asymmetric [3+2] cycloaddition of α,β -unsaturated aldehydes to azomethine imines **116** was carried out using the α,α -diarylprolinol salt **239**. The enal activation takes place by iminium formation giving the corresponding fused pyrazolidinones **238** mainly with *exo*-selectivity and high enantioselectivities (Scheme 92).¹⁴⁰ The possible reaction models for this 1,3-DC is illustrated in Scheme 92: both transition states **A** and **B** with *s*-*cis* and *s*-*trans* conformations, respectively, would afford the *exo*-cycloadducts.

63

Scheme 92 Organocatalyzed enantioselective [3+2] cycloaddition of azomethine imines 166 with enals.

Α

В

When this reaction is catalyzed by *N*-heterocyclic carbenes, a highly stereoselective formal [3+3] cycloaddition takes place to provide pyridazinones **240** (Scheme 93).¹⁴¹ The addition of the *N*-mesitylbenzimidazolyl carbene, generated from the benzimidazolium iodide **242**, by an addition/acylation sequence with **166** affords the final bicyclic heterocycles **240**.

Scheme 93 NHC-catalyzed [3+2] cycloaddition of azomethine imines 166 with enals.

The enantioselective [3+2] cycloaddition of cyclic enones and azomethine imines **166** has been performed in the presence of the chiral primary amine 9-amino-9-deoxyepiquinine **244** and 2,4,6-triisopropylbenzenesulfonic acid (TIPBA) as catalyst (Scheme 94).¹⁴² The corresponding tricyclic pyrazolidinones **243** were obtained in good yields, diastereo- and enantioselectivities. The *Cinchona* derived catalyst activates the enone forming a ketiminium cation and an additional hydrogen bonding between the OH and the C=O groups to produce the *endo* and *Re*-face selectivities in the final cycloadducts.

Scheme 94 Enantioselective organocatalyzed [3+2] cycloaddition of cyclic enones to 166.

The base-catalyzed diastereoselective [3+3] annulations of 3-isothiocyanatooxindoles **245** to azomethine imines **166** gave 3,3'-triazinnyl spirooxindoles **246** (Scheme 95).¹⁴³ Using 1 mol% of triethylamine the reaction takes place in only five minutes at room temperature with high yields and diastereoselectivities.

Scheme 95 Base-catalyzed [3+3] cycloaddition of isothiocyanatooxindoles 245 with 166.

Another example of a base-catalyzed [3+3] cycloaddition of azomethine imines **166** takes place with 1,4-dithiane-2,5-diol **247**. DABCO catalyzes this process (Scheme 96) in methanol giving products **248** resulting from the attack of the base to mercaptoacetaldehyde followed by addition to the azomethine imine and subsequent intramolecular cyclization, the diastereoselectivity

being controlled by the anomeric effect.¹⁴⁴ 5-Methyl and 5-phenyl substituted azomethines **166** gave the all *cis*-cycloadducts **248**.

Scheme 96 DABCO-catalyzed [3+3] cycloaddition of mercapto acetaldehyde to 166.

The multicomponent synthesis of pyrazolidinones **249** has been performed starting from **165**, the aldehyde and Meldrum's acid. This process was organocatalyzed by $(DHQ)_2PHAL$ **250** acting as chiral base. A domino Knoevenagel-aza-Michael-cyclocondensation reaction gave the resulting cycloadducts **249** in good yields and enantioselectivities (Scheme 97).¹⁴⁵

Scheme 97 Multicomponent enantioselective [3+2] cycloaddition of pyrazolidinones 165 with aldehydes and Meldrum's acid.

Nucleophilic phosphine catalysis has been used for different types of [3+n] cycloaddition of azomethine imines **166** with allenoates **77** (Scheme 98). These reactions take place by formation of various zwiterionic intermediates by addition of a phosphine as Lewis base to the β -carbon of the α -allenic ester, affording five -, six-, seven-, and eight-membered dinitrogen containing heterocycles. These types of cycloadditions have been also studied with C,N-cyclic azomethine imines **57** (Scheme 27).⁴²

Scheme 98 Phosphine-catalyzed [3+n] cyclization of azomethine imines 166 with allenoates.

Ethyl 2-methylbuta-2,3-dienoate **75** reacted with azomethine imines **166** under tri-*n*butylphosphine-catalyzed [3+2] cycloaddition to afford the exocyclic alkylidene adducts **251** as single isomers (Scheme 99).¹⁴⁶ By using a chiral phosphine **253**, product **251** (with $R^1 = Ph$) was obtained in 56% yield and 89% ee. When azomethine imine **166** [with $R = 4-(O_2N)C_6H_4$] was allowed to react with other α-alkyl allenoates **75**, trimethylphosphine was the catalyst of choice to prepare products **252**. These 1,3-DC takes place by formation of the corresponding 1,3-zwiterionic intermediate **254**.

Scheme 99 Phosphine-catalyzed [3+2] cycloadditions of allenoates 75 with azomethine imines 166.

The reaction involving diethyl 2-vinylidene succinate **255** was more complicated giving mixtures of five-, six-, and seven-membered ring either with tri-*n*-butyl- or trimethylphosphine (Scheme 100).¹⁴⁶ It has been proposed that zwiterionic intermediates **A** and **B** gave the five- and the six- or seven-membered ring, respectively.

Scheme 100 Phosphine-catalyzed [3+2], [3+3] and [4+3] cycloadditions of azomethine imine 166 and diethyl 2-vinylidene succinate 255.

For unsubstituted ethyl 2,3-butadienoate **260**, a mixture of [3+2] and [3+3] cycloadditions **261** and **262** are formed in different proportions depending on the phosphine used as catalyst. Trimethylphosphine favors the formation of the tetrahydropyrazolopyrazolopyrazolope **261** and tri-*n*-butylphosphine the tetrahydropyrazolopyridazinone **262** by addition of the γ -carbon of the allenoate and the α -carbon, respectively (Scheme 101).¹⁴⁶

Scheme 101 Phosphine-catalyzed [3+2] and [3+3] cycloaddition of azomethine imine 166 and ethyl 2,3-butadienoate 260.

When γ -substituted allenoates 77 are allowed to react with azomethine imine **166** [Ar = 4-(O₂N)C₆H₄] only the tetrahydropyrazolopyridazinones **263** were obtained in modest yields and with total diastereoselectivity, among other non-isolated products (Scheme 102).¹⁴⁶

Scheme 102 Phosphine-catalyzed [3+3] cycloaddition of 166 with γ -substituted allenoates 77.

The reaction of ethyl 2,3-butadienoate **260** with different azomethine imines **166** was studied in more detail in order to determine the structure of secondary products. It was found out the formation of [3+2+3] products, such as 1-oxo-2,3,5,6-tetrahydro-1*H*-pyrazolo[1,2-a][1,2]diazines **264** and **265**, mainly when tricyclohexylphosphine was used as catalyst (Scheme 103).¹⁴⁶ In this case, experimental and theoretical studies support the participation of 1,5-zwiterionic intermediates **266**, in order to explain the formation of the eight- and seven-membered rings through [5+3] and [5+2] cycloadditions, respectively.¹⁴⁷

Scheme 103 Phosphine-catalyzed [5+3] cycloaddition of 166 with ethyl 2,3-butadienoate.

However, under thermal conditions, only the [3+2] cycloaddition products **267** were formed in high yields (Scheme 104).⁴¹ Whereas with α -, and γ -substituted allenoates a complex mixture of products was obtained. When ethyl 2-butynoate was used instead of ethyl 2,3-butadienoate (**260**), the tri-*n*-butylphosphine-promoted cyclization with azomethine imines **166** afforded also a mixture of products **261** and **262** by intermediacy of the same 1,3-zwiterionic intermediate **254**.¹⁴⁸

Scheme 104 Thermal [3+2] cycloaddition of 166 with ethyl 2,3-butadienoate 260.

Electron-deficient alkenes such as the (*Z*)-1,2-bis(phenylsulfonyl)ethylene **268** gave under Ph_2PMe -catalysis at room temperature the corresponding [3+2] cycloaddition products **269** in the reaction with azomethine imines **166** (Scheme 105).¹⁴⁹ Products **269** were obtained with high diastereoselectivity and the relative configuration was the same when using (*E*)-**268**. In this case, the participation of the zwiterionic intermediate **270** has been proposed, which attacks the azomethine imine followed by intramolecular cyclization regenerating the phosphine. The same [3+2] cycloaddition has been observed with C,N-cyclic azomethine imines **57**, as well as with **144** and **156**.

Scheme 105 Phosphine-catalyzed [3+2] cycloaddition of 166 with (Z)-bis-1,2-bis(phenylsulfonyl)ethylene 268.

Chiral bis-phosphoric acid **272** has been used as Brøsted acid catalyst for the 1,3-DC of alkylideindolinones **271** with azomethine imines **166** to afford spiro pyrazolidin-3,3'-oxindoles **273** (Scheme 106).¹⁵⁰ By MS and DFT calculation experiments the best transition state has been established in which both the alkylideneindolines and the azomethine imines are hydrogen bounded with the OH group of both phosphoric acid moieties.

Scheme 106 Phosphoric acid-catalyzed the enantioselective [3+2] cycloaddition of 166 with alkylideneindolinones.

The phosphoric acid **30** (Ar = 9-anthracenyl) has shown good diastereo- and moderate enantioselectivities in the organocatalyzed enantioselective inverse-electron-demanding 1,3-DC of azomethine imines **166** with *o*-hydroxy- α -methylstyrene **274**. Thus, [3+2] cycloaddition takes place in 1,3-difluorobenzene giving mainly cycloadducts **275** through a two-step mechanism. The presence of the hydroxy group at the *ortho* position is crucial for the reaction to occur. A dual activation mode by hydrogen bonding interaction between the two substrates and the catalyst together with the conjugative effect initiated by the *o*-hydroxy group played an essential role in the proposed transition state **A** (Scheme 107).¹⁵¹

Scheme 107 Phosphoric acid-catalyzed enantioselective [3+2] cycloaddition of 166 with *o*-hydroxy-α-methylstyrene 274.

4.2 N-Alkylidenepyrazolidin-1-ium-2-ides

Azomethine imines **277** can be generated from the opening of the diaziridine ring in 1,5diazabicyclo[3.1.0]hexane **276** either by thermolysis¹⁵²⁻¹⁵⁴ or by means of scandium triflate and trapped by dipolarophiles to give products **278** (Scheme 108).^{155,156} This ring opening can be performed in ionic liquids (ILs) in the presence of BF₃·Et₂O and the resulting unstable azomethine imines can be trapped by nitro styrenes or chalcone to give the corresponding [3+2] cycloadducts **278** and **280**, respectively (Scheme 109).¹⁵⁷

Scheme 108 [3+2] Cycloadditions of azomethine imines 277 generated from 1,5diazabicyclo[3.1.0]hexanes 276.

Scheme 109 [3+2] Cycloaddition of azomethine imines 277 with nitro styrenes and chalcone.

When acrylonitrile or 4-nitrophenyl vinyl sulfone were used as dipolarophiles the corresponding cycloadducts **281** or **282** were obtained with modest diastereoselectivity, and with opposite regioselectivity in the first case (Scheme 110).^{158,159}

Scheme 110 [3+2] Cycloaddition of azomethine imines 276 with acrylonitrile and 4-nitrophenyl vinyl sulfone.

4.3 N-Alkylidene 3-oxodiazolidin-1-ium-2-ides

These type of azomethine imines has been less studied than the pyrazolidinium imides. Only glyoxylic azomethine imines derived from **283** have been investigated. These chiral six-membered hydrazide **283** react with aliphatic and aromatic aldehydes to give the corresponding azomethine imines, which react with diethyl acetylene dicarboxylate and olefinic dipolarophiles to provide pyrazolo[1,2-*a*]pyridazin-5(6*H*)-ones.^{10,160,161} When ethyl glyoxylate is used as carbonyl component in the presence of an excess of magnesium bromide etherate, the corresponding oxadiazolidine **284** is formed, which undergoes cycloreversion-cycloaddition in the presence of various electron-poor dipolarophiles such as styrenes giving cycloadducts **285** (Scheme 111).¹⁶² Methyl maleate, fumarate and crotonate as well as *N*-phenylmaleimide gave cycloadducts **286-289** with modest diasteroselectivities and good yields.

Scheme 111 Diastereoselective [3+2] cycloadditions of chiral glyoxylic azomethine imine.

Conclusions

In the last 10 years the chemistry of acyclic and especially cyclic azomethine imines, have experimented a renaissance in synthesis of heterocycles of wide structural diversity such as pyrazolidines, pyrazoloisoquinolines and pyrazolopyrazolones among others. Their reactivity in 1,3-dipolar cycloadditions (1,3-DC) with a great variety of dipolarophiles in high regio- and diastereoselectively manner have found many applications in the synthesis of dinitrogen heterocycles. Depending on the dipolarophile partially or totally saturated heterocycles can be prepared generally by a [3+2] cycloaddition but also by higher order cycloadditions. Most of the methodologies recently studied are in the field of the asymmetric synthesis using chiral Lewis bases and Brønsted acids as organocatalysts depending on the dipolarophile and metal complexes bearing chiral ligands. The study of asymmetric catalytic methods has just started and further synthetic applications to be developed in this field would be important in the next future.

Carmen Nájera was born in Nájera (La Rioja) and was graduated from the University of Zaragoza in 1973, obtaining her doctorate in chemistry from the University of Oviedo in 1979. She spent postdoctoral stays at the ETH (Zurich), the Dyson Perrins Laboratory (Oxford), Harvard University, and Uppsala University. She became Associate Professor in 1985 at the University of Oviedo and Full Professor in 1993 at the University of Alicante. She is coauthor of more than 300 papers and book chapters and has supervised more than 40 PhD students. She has been awarded with the 2006 Organic Chemistry Prize from the Spanish Royal Chemical Society of Chemistry, the 2006 Rosalind Franklin International Lectureship from the English Royal Society, the SCF 2010 French-Spanish Prize from the Société Chimique de France and the IUPAC 2015 Distinguished Women in Chemistry or Chemical Engineering Award. In 2012 she was named full Member of the Royal Spanish Academy of Sciences, and was appointed as Active Member of the European Academy of Sciences and Arts.

José Miguel Sansano studied chemistry at the University of Alicante, where he obtained his B.Sc. and Ph.D. degrees in 1988 and 1994, respectively. His Thesis was supervised by Prof. C. Nájera and dealt about sulfone chemistry. After spending a two-year postdoctoral stay at the University of Leeds (U.K.) with Prof. R. Grigg, he joined the University of Alicante in 1996, where he was appointed Associate Professor in 2001. In 2010 he was promoted to Professor in the same University.

Miguel Yus was born in Saragossa in 1947 and received his BSc (1969), MSc (1971) and PhD (1973) from the University of Saragossa. After spending two years as a postdoctoral fellow at the Max Plack Institut in Mülheim he became Associate Professor (1977) and Professor (1987) at the University of Oviedo. In 1988 he moved to his current position at the University of Alicante. He has been invited professor at ETH-Zürich, Oxford, Harvard, Uppsala, Tucson, Okayama, Paris, Strasbourg, Bologna, Sassari, Tokyo and Kyoto. Dr. Yus has authored more than 500 papers and five patents, has delivered around 200 lectures abroad and has supervised more than 60 PhD students. Among others he has receive the Spanish-French Prize (1999), twice the Japan Society for the Promotion of Science Prize (2000, 2007), the Stiefvater Memorial Lectureship Award (2001), the Conference Lourenco-Madinaveitia (1912), the Serratosa Lecctureship (2010) and the Medalla Felix Serratosa (2012), being Academician of the European Academy of Sciences and Arts (2012). He has been in the Advisory Bord of about 20 international journals and founded ten years ago the company MEDALCHEMY for the commercialization of fine chemicals.
