This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

*Accepted Manuscripts* are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. This *Accepted Manuscript* will be replaced by the edited, formatted and paginated article as soon as this is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

1 **Ag Modified AgI-TiO<sub>2</sub> as an Excellent and Durable Catalyst**  
2 **for Catalytic Oxidation of Elemental Mercury**

3  
4 Songjian Zhao, Zan Qu, Naiqiang Yan\*, Zhen Li, Wenfei Zhu, Jie pan, Jianfang Xu,  
5 Mengdan Li,  
6

7 AgI-TiO<sub>2</sub> was employed for the removal of elemental mercury (Hg<sup>0</sup>) in flue gas, and extra  
8 elemental silver (Ag) was introduced to enhance the catalytic activity and stability. AgI-TiO<sub>2</sub>  
9 displayed an excellent effect on Hg<sup>0</sup> catalytic oxidation, and the Hg<sup>0</sup> oxidation efficiency was  
10 almost 100% with only 5 ppm HCl at 350°C, which was better than that of KI-Ti. Adding Ag to  
11 AgI-TiO<sub>2</sub> can prolong the time of high efficiency notably, and the Hg<sup>0</sup> oxidation efficiency was  
12 still above 90% after 10 h with only 2% Ag added. Doping with silver could suppress the  
13 decomposition of AgI and the loss of iodine, which keep the stability of the catalyst performance.  
14 Besides, HCl was readily adsorbed and activated by silver. Iodine in Ag(2%)-AgI-Ti mainly acted  
15 as an accelerant for Hg<sup>0</sup> oxidation by facilitating formation of the intermediates Hg-I\*, then,  
16 chlorine can further convert the intermediate to HgCl<sub>2</sub> as the final product. In addition, the  
17 thermogravimetric (TG) analysis proved that Ag(2%)-AgI-Ti manifested a good stability at high  
18 temperature. Furthermore, the ion chromatograms tests also manifested the chemical stability of  
19 AgI-Ti in the presence of Ag.

## 22 Introduction

23 The emission of mercury from coal-fired power plants has attracted increasing  
24 concern in recent years because of the high toxicity, volatility and bioaccumulation.<sup>1</sup>  
25 The Minamata Convention on Mercury, which has been signed by most countries in  
26 October 2013, will be put into force to prevent Hg emission worldwide.<sup>2,3</sup> As one of  
27 the largest mercury emission countries, China has also paid increasing attention to  
28 mercury control. And the government has issued “Emission Standard of Air  
29 Pollutants for Thermal Power Plants” (GB13223-2011) to reduce mercury emissions,  
30 which was just implemented in January 2015.<sup>4</sup>

31 Generally, mercury exists in three forms in coal-fired flue gas: elemental ( $\text{Hg}^0$ ),  
32 oxidized ( $\text{Hg}^{2+}$ ), and particle-bound ( $\text{Hg}^{\text{p}}$ ).<sup>5</sup>  $\text{Hg}^{2+}$  and  $\text{Hg}^{\text{p}}$  are relatively readily to be  
33 removed from flue gas by using typical air pollution control devices, such as ESPs  
34 and wet-FGD.<sup>6</sup> However,  $\text{Hg}^0$  is difficult to be removed from flue gas due to its high  
35 volatility and low solubility in water.<sup>7</sup> The technologies for the abatement of  $\text{Hg}^0$   
36 mainly focus on two methods: enhanced adsorption or oxidation. The adsorption  
37 process, such as halid-modified activated carbon injection, is expensive and may  
38 cause secondary environmental problems.<sup>8,9</sup> Consequently, the catalytic oxidation  
39 process is a promising choice, and the generated  $\text{Hg}^{2+}$  can be subsequently captured  
40 by the existing air pollution control devices.

41 It is reported that HCl is an important specie that affects mercury oxidation,  
42 because the major oxidized mercury specie in coal-fired flue gas is  $\text{HgCl}_2$ .<sup>10</sup> Other  
43 halogen species could also oxidize  $\text{Hg}^0$ , such as bromine<sup>11,12</sup> and iodine, and iodine

44 was found to be the most efficient oxidant.<sup>13</sup> In addition, HCl would react with HI or  
45 I<sub>2</sub> to generate interhalogen specie (ICl), which was a very efficient oxidant for Hg<sup>0</sup>  
46 oxidation.<sup>13, 14</sup> However, iodine release might bring unexpected pollution problems if  
47 too much iodine was used in flue gas, and I<sub>2</sub> sublimated at a relatively low  
48 temperature.

49 Silver has been recognized as an active catalytic element and subsequently used  
50 in various catalysts.<sup>7, 15</sup> Ag was also used as adsorbent materials to remove Hg<sup>0</sup> at low  
51 temperatures through an amalgamation mechanism. Besides, Ag can generate  
52 electrophilic oxygen, which was beneficial for the reaction. The combination of silver  
53 and iodine might enhance the efficiency of Hg<sup>0</sup> oxidation.

54 In addition, AgI is also a very important catalyst extensively used in photography  
55 and photocatalysis field. However, AgI was unstable due to the fact that it would  
56 decompose into Ag when exposed to light. Many studies have shown that the metallic  
57 silver species existed on the surface were able to inhibit the decomposition of AgX,  
58 so adding silver could enhance the catalytic activity and stability.<sup>16, 17</sup> Furthermore, it  
59 has found that AgI can maintain its stability when loaded on a semiconductor support  
60 such as TiO<sub>2</sub>.<sup>18</sup> Therefore, Ag Modified AgI-TiO<sub>2</sub> might be used for catalytic  
61 oxidation of elemental mercury. However, no report regarding Ag modified AgI-TiO<sub>2</sub>  
62 catalyst for the Hg<sup>0</sup> removal can be acquired as yet.

63 In the present study, catalysts were prepared using a room-temperature  
64 impregnation method. The physical and chemical properties of the catalysts, as well  
65 as the Hg<sup>0</sup> oxidation efficiency of the Ag modified AgI-TiO<sub>2</sub> catalyst at low HCl

66 concentrations, were investigated. Furthermore, the catalytic mechanism involved in  
67 improving the efficiency was discussed.

68

## 69 **Experimental section**

### 70 **Samples preparation**

71 Catalysts were prepared by the impregnation method, which included KI-TiO<sub>2</sub>,  
72 AgI-TiO<sub>2</sub>, Ag-AgI-TiO<sub>2</sub>. For the preparation of KI-TiO<sub>2</sub>, an appropriate amount of  
73 TiO<sub>2</sub> powder (Degussa P25) and KI were mixed to stir for 1 h, which was marked as  
74 A solution, then the A solution was dried with the rotary evaporation apparatus,  
75 finally calcined in a muffle furnace (5 h, 500 °C); For AgI-TiO<sub>2</sub> and Ag-AgI-TiO<sub>2</sub>:  
76 PVP and AgNO<sub>3</sub> precursor were mixed and stirred for 6 h at room temperature,  
77 which was added by drops into A solution and stirred constantly for 2 h, then the  
78 mixed solution was dried and calcined as above, and the difference between  
79 AgI-TiO<sub>2</sub> and Ag-AgI-TiO<sub>2</sub> was that the stoichiometry of Ag.to iodide was more  
80 than 1.0 for the latter. The KI-TiO<sub>2</sub>, Ag-TiO<sub>2</sub> and Ag-AgI-TiO<sub>2</sub> catalysts are labeled  
81 as KI-Ti, Ag-Ti and Ag-AgI-Ti. The element of proportion of the Ag or I to TiO<sub>2</sub> is  
82 on the basis of the atom percentages, such as Ag(x%)-Ti represents Ag/TiO<sub>2</sub> mole  
83 ratio, and 1% was omitted.

### 84 **Catalytic Activity Evaluation**

85 The catalytic activity evaluation of the catalysts was similar to that described  
86 previously.<sup>7</sup> It consisted of a simulated gas preparation system, catalytic reaction  
87 device, a cold vapor atomic absorption spectrometer (CVAAS) and an online data

88 acquisition system.  $\text{Hg}^0$  vapor was prepared from the  $\text{Hg}^0$  permeation unit and was  
89 blended with the gases before entering the reactor. And the concentration of elemental  
90 mercury in the gas was analyzed using a mercury analyzer (CVAAS SG-921). The gas  
91 containing the elemental mercury was firstly passed through the bypass and then sent  
92 to the CVAAS to determine the baseline. When the concentration of elemental  
93 mercury fluctuated within  $\pm 5\%$  for more than 30 min, the gas was shifted to the  
94 catalytic reactor with catalysts. When the catalyst was saturated by  $\text{Hg}^0$ , 5 ppm HCl  
95 was passed to estimate the  $\text{Hg}^0$  oxidation efficiency. Because the catalysts were first  
96 saturated in about  $300 \mu\text{g}/\text{m}^3$  of  $\text{Hg}^0$  with  $\text{N}_2$  and  $\text{O}_2$  gas flow, the decrease of  $\text{Hg}^0$   
97 concentration across the catalysts after passing HCl was attributed to  $\text{Hg}^0$  oxidation.  
98 Therefore, the definition of  $\text{Hg}^0$  oxidation efficiency (Eoxi) over catalysts is as  
99 follows:

$$100 \quad \text{Eoxi}(\%) = \frac{\Delta\text{Hg}^0}{\text{Hg}_{\text{in}}^0} = \frac{\text{Hg}_{\text{in}}^0 - \text{Hg}_{\text{out}}^0}{\text{Hg}_{\text{in}}^0}$$

101 The gas flow rate was corresponded to a space velocity (SV) of  $4.26 \times 10^5 \text{ h}^{-1}$ .  
102 Nitrogen was used as the carrier gas, and the oxygen content was set at 4%.

### 103 **Characterization of the Catalysts**

104 Powder X-ray diffraction pattern was recorded between  $10^\circ$  and  $80^\circ$  at a step of  $7^\circ$   
105  $\text{min}^{-1}$  on an X-ray diffractionmeter (APLX-DUO, BRUKER, Germany) using Cu Ka  
106 radiation (40 kv and 20 mA). The microstructure of catalysts was analyzed by  
107 transmission electron microscopy (TEM). Samples were dispersed in ethanol with a  
108 strong sonication before the analysis.  $\text{H}_2$ -TPR experiments were performed on  
109 Chemisorp TPx 2920 instrument, the catalysts were degassed at  $200^\circ \text{C}$  for 3 h under

110 Ar at atmosphere before H<sub>2</sub>-TPR test, the reducing gas was 10% H<sub>2</sub>/Ar. The X-ray  
111 photoelectron spectroscopy (XPS) measurement was done with an AXIS  
112 UltraDLD(Shimadzu-Kratos) spectrometer with Al Ka as the excitation source. The  
113 C1s line at 284.8 eV was taken as a reference for the binding energy calibration. The  
114 reaction by passing 5000 ppm HCl was monitored in-situ by a UV/vis spectrometer  
115 (BDS130, USA) equipped with an optical fiber for UV-beam transmission and a  
116 detector in the range of 200-800 nm. The maximum adsorption of UV for iodine,  
117 iodine monochloride and chlorine was around at the wavelength of 530 nm, 467 nm  
118 and 330 nm, respectively.<sup>19</sup> The reaction product were dissolved into the ultrapure  
119 water and analyzed by ion chromatography (BP-100). The thermal stability of  
120 catalysts was performed by the TGA/DSC1 (Mettler Toledo), N<sub>2</sub> was as carrier gas,  
121 and the heating rate was 5 °C/min. Hg<sup>0</sup> adsorption experiment was conducted by  
122 passing flue gas contained Hg<sup>0</sup>, N<sub>2</sub> and 4% O<sub>2</sub> into prepared catalyst, and recording  
123 the Hg<sup>0</sup> signal curve. The temperature programmed desorption(TPD) curves of Hg<sup>0</sup>  
124 proceeded as follows: an appropriate amount of catalyst was placed in fixed-bed  
125 reactor with N<sub>2</sub> + 4% O<sub>2</sub> at 30 L/h and 100 °C to adsorb mercury for 2 h; afterwards,  
126 the oxygen was stopped, and the Hg<sup>0</sup> signal curve was recorded at 2 °C/min until  
127 450 °C under nitrogen.

128

## 129 **Results and discussion**

### 130 **Comparison of the Hg<sup>0</sup> catalytic oxidation efficiencies of various catalysts**

131

132

**Figure 1**

133

134 Figure 1 shows the comparison of the  $\text{Hg}^0$  catalytic oxidation efficiencies over  
135 various catalysts at 350 °C. The  $\text{Hg}^0$  oxidation efficiency of AgI-Ti was higher than  
136 that of KI-Ti, which indicated that there were more active species to oxidize  $\text{Hg}^0$  after  
137 HCl was passed for AgI-Ti. While the  $\text{Hg}^0$  oxidation efficiency was reduced with time,  
138 suggested that the performance of AgI-Ti was unstable. When silver was added, the  
139 high efficiency time was obviously prolonged. However, the efficiency was declined  
140 for high silver content, which might be that high content of silver inhibited the  
141 catalysis of AgI. And 2% Ag content was suitable. The  $\text{Hg}^0$  oxidation efficiency was  
142 still above 90% after 10 h, indicated that Ag(2%)-AgI-Ti was a high-performance  
143 catalyst for the  $\text{Hg}^0$  catalytic oxidation. Besides, the  $\text{Hg}^0$  catalytic performance of  
144 Ag(1%)-AgI-Ti was better than that of Ag(1%)-AgCl-Ti and Ag(1%)-AgBr-Ti,  
145 manifested that iodine was the most efficient for  $\text{Hg}^0$  oxidation among halogen  
146 species. Therefore, the physical and chemical properties of the catalysts and the  
147 reaction mechanism were necessary to study.

**Catalysts activity**

149

150

**Figure 2**

151

152 Figure 2 shows the  $\text{Hg}^0$  oxidation efficiencies over Ag(2%)-AgI-Ti at various  
153 temperatures after passing 5 ppm HCl. As can be seen from Figure 2, the catalytic

154 efficiency of Ag(2%)-AgI-Ti was improved with the increase of temperature, and the  
155 Hg<sup>0</sup> oxidation efficiency could reach 100% above 350 °C. It indicated that the  
156 suitable reaction temperature for oxidizing Hg<sup>0</sup> was at high temperature, and there  
157 were more active species to oxidize Hg<sup>0</sup> at high temperature.

158

159

### Figure 3

160

161 The Hg<sup>0</sup> catalytic oxidation efficiencies of Ag(2%)-AgI-Ti with various cases are  
162 showed in Figure 3. Ag(2%)-AgI-Ti had little catalytic ability in the condition of only  
163 O<sub>2</sub> or HCl. And when O<sub>2</sub> and HCl coexisted, the oxidation efficiency was high,  
164 manifested that HCl was the mainly catalytic component. Active Cl or Cl<sub>2</sub> would be  
165 generated by the catalysis of Ag(2%)-AgI-Ti with the presence of O<sub>2</sub>, which could  
166 react with AgI to produce ICl or I<sub>2</sub> to oxidize Hg<sup>0</sup>. When 500 ppm SO<sub>2</sub> was passed,  
167 the performance of catalyst was slightly inhibited, which might be that some of active  
168 Cl would react with SO<sub>2</sub>.<sup>13</sup> And the efficiency improved slightly when adding 500  
169 ppm NO, indicated NO promoted the Hg<sup>0</sup> oxidation.<sup>20</sup> In addition, 4% H<sub>2</sub>O was little  
170 effect on the Hg<sup>0</sup> oxidation.

171

### 172 Microstructural characterizations

173

174

### Figure 4

175

### Table 1

176 To obtain the microscopic morphologies information, transmission electron  
177 microscopy (TEM) analyses of the AgI-Ti and Ag(2%)-AgI-Ti nanoparticles were  
178 carried out, as shown in Figure 4. The AgI-Ti catalyst was nanoparticles and the sizes  
179 were between 20 and 40 nm from Figure 4 (a). The element content of AgI-Ti by the  
180 EDS analysis in table 1 could prove the existence of AgI on the carrier. Besides, the  
181 HRTEM image in Figure 4 (b) corresponding to the circled in Figure 4 (a) shows the  
182 crystal lattices with distances of 0.23 nm and 0.35 nm, which can be attributed to the  
183 (110) plane of  $\beta$ -AgI and the (1 0 1) plane of anatase  $\text{TiO}_2$ , respectively, to further  
184 prove the existence of AgI on the  $\text{TiO}_2$ .<sup>21 22</sup> There were many small particles attached  
185 on the surfaces of  $\text{TiO}_2$  in Figure 4 (c), which was Ag nanoparticles compared with  
186 Figure 4 (a). And the AgI nanoparticles were also found by HRTEM image in Figure 4  
187 (d) corresponding to the circled in Figure 4 (c). Besides, the content of iodine for  
188 Ag-(2%)-AgI-Ti was higher than that of AgI-Ti according to the result of table 1. It  
189 indicated that the catalyst was prepared successfully and adding the silver could  
190 inhibit the decomposition of AgI efficiently.

### 191 X-ray diffraction study

192

193

### Figure 5

194

195 Figure 5 shows the XRD patterns of the various catalysts calcined at 500 °C.

196 The anatase and the rutile phases of  $\text{TiO}_2$  can be seen for all catalysts in Figure 5. The

197 peak at 32.8 eV was indexed to (1 0 2) planes of the hexagonal  $\beta$ -AgI crystal phase<sup>16</sup>,

198 which was weak in Figure 5 (b-d) due to the low content. Additionally, no noticeable  
199 silver oxide and metal peaks were observed in the X-ray diffractograms in Figure 5 (b)  
200 and (c), because the amount of Ag dopant was low or the strongest Ag peak (1 1 1)  
201 was overlapped with that of anatase (0 0 4). The Ag<sup>0</sup> characteristic peaks could be  
202 observed in Figure 5 (d), indicated that additive silver was loaded on the support in  
203 the form of metallic state.

204

### 205 XPS analysis

206

207

### Figure 6

208

209 Figure 6 shows the XPS spectra of AgI-Ti and Ag(2%)-AgI-Ti over the spectral  
210 regions of Ag 3d, I 3d, O 1s, Ti 2p, Cl 2p and Hg 2p. The spectra of I 3d in Figure 6 (a)  
211 shows that the binding energies of I 3d<sub>5/2</sub> and I 3d<sub>3/2</sub> were located at about 630.5 eV  
212 and 618.5 eV, respectively, which could be ascribed to the I<sup>-</sup> in AgI.<sup>23, 24</sup> The I 3d  
213 peaks of Ag(2%)-AgI-Ti were enhanced compared with that of AgI-Ti, suggested that  
214 the content of iodine was higher for Ag(2%)-AgI-Ti. It indicated that the addition of  
215 silver could maintain the stability of AgI and was beneficial for the catalytic reaction.  
216 After passing HCl, the strength of I 3d peaks was weakened, which might be that Hg<sup>0</sup>  
217 or Cl species was adsorbed on the surface of iodine.

218 Figure 6 (b) shows the XPS peaks of Ag 3d. It was reported that the peaks at  
219 367.90 eV and 373.94 eV were attributed to Ag (I), and those at 368.23 eV and 374.09

220 eV were attributed to metallic silver Ag (0).<sup>21</sup> It could find that the silver  
221 nanoparticles were present in a mixture of metallic silver (Ag<sup>0</sup>) and Ag<sup>+</sup> (AgI) for  
222 AgI-Ti and Ag(2%)-AgI-Ti, in which the Ag<sup>+</sup> was dominant, manifested the existence  
223 of AgI, and it could also conclude that some of AgI was decomposed to Ag<sup>0</sup>. By  
224 adding silver to AgI-Ti, the more content of metallic silver could stabilize AgI, so that  
225 the Ag<sup>+</sup> peak intensity of Ag(2%)-AgI-Ti was increased. After passing HCl, the  
226 intensity of the characteristic peaks was weakened. It might because HCl or Cl was  
227 adsorbed on the surface of Ag. The characteristic peak of silver was shifted to low  
228 binding energy due to the effect of HCl.

229 The O 1s XPS spectrum is shown in Figure 6 (c). The peak at 529.8 eV might be  
230 ascribed to lattice oxygen, and the peak at 531.4 eV could be attributed to surface  
231 chemisorbed oxygen. Besides, the peak at 528.2 eV was nucleophilic states and 530.4  
232 eV denoted electrophilic states for the O 1s, and the electrophilic oxygen was  
233 beneficial for oxidation reaction.<sup>7</sup> It could be found from Figure 6 (c) that there was  
234 no nucleophilic oxygen after adding silver, and the chemisorbed oxygen and  
235 electrophilic oxygen existed, which was beneficial for the oxidation ability of catalyst.  
236 And when the HCl was passed, the surface chemisorbed oxygen was decreased,  
237 suggested that HCl and oxygen were activated by silver and reacted with each other.  
238 The reaction path might be that the electron of HCl transferred by silver to the  
239 chemisorbed oxygen. Active chlorine was produced and then oxidized I<sup>-</sup> or Hg<sup>0</sup>, and  
240 generated oxygen anion combined with hydrogen ions into water.<sup>17</sup>

241 The two typical Ti 2p peaks located at approximately 458.56 eV and 464.24 eV

242 can be assigned to  $\text{Ti}^{4+} 2p_{3/2}$  and  $\text{Ti}^{4+} 2p_{1/2}$ , respectively in Figure 6 (d).<sup>25</sup> An  
243 additional peak at 457 eV for AgI-Ti in Figure 6 (d) was detected that matched the  
244 trivalent state of titanium,<sup>25</sup> which was disappeared for Ag(2%)-AgI-Ti. And an  
245 obvious shoulder at about 460.4 eV was also attributed to  $\text{Ti}^{4+} 2p_{3/2}$ ,<sup>26</sup> shown in  
246 Figure 6 (d). It indicated that the surface-deposited Ag could induce a change in the Ti  
247 chemical states, maintaining the higher oxidation states of Ti.

248 The Cl 2p XPS spectrum is shown in Figure 6 (e). There were two peaks at 197.8  
249 and 199.7 eV for Cl 2p, which were attributable to ionic ( $\text{Cl}^-$ ) and covalent ( $-\text{Cl}$ )  
250 chlorine species, respectively.<sup>27</sup> The ionic chlorine ( $\text{Cl}^-$ ) might be the  $\text{HgCl}_2$  generated  
251 by the reaction of chlorine species and mercury or chlorine species and  $\text{HgI}_2$ .<sup>19</sup> And  
252 the covalent ( $-\text{Cl}$ ) chlorine species might be the adsorbed HCl or generated ICl.

253 The Hg 4f XPS patterns are shown in Figure 6 (f). As can be found the peak of  
254 Hg 4f was at about 101.8 eV, which was significantly higher than the binding energy  
255 of  $\text{Hg}^0$  (99.9 eV).<sup>28</sup> It inferred that there was no  $\text{Hg}^0$  on the surface of catalyst. Tao, et  
256 al. reported that the binding energies for Hg 4f 5/2 and Hg 4f 7/2 can be attributed to  
257 HgO (with the peak at 104.4 eV) and  $\text{HgCl}_2$  (101.4 eV).<sup>29</sup> The Hg 4f peak in Figure 6  
258 (f) could be  $\text{Hg}^{2+}$ , indicated that  $\text{Hg}^0$  was oxidized by the catalyst. Besides, the Hg 4f  
259 was weak, which was suggested that the reaction production was adsorbed less on the  
260 surface of catalyst, and most of mercury oxidation was in the gas.

#### 261 **TPR analysis**

262

263

**Figure 7**

264

265 The TPR profiles of the various catalysts are shown in Figure 7. As can be seen  
266 in the Figure 7, p25 was no obvious peak, and the oxidation ability was weak. There  
267 was a peak at about 600 °C for KI-Ti, showed that catalyst started to decompose to  
268 form I<sub>2</sub> under this temperature. In addition, it can be seen clearly that the oxidation  
269 ability of AgI-Ti and Ag(2%)-AgI-Ti was higher than that of KI-Ti and the catalytic  
270 performance was stable. And the peak at 180 °C was stronger for Ag(2%)-AgI-Ti,  
271 which might be due to the larger proportion of Ag<sup>0</sup>, easier to produce active hydrogen  
272 and hydrogen overflow or Ag<sub>2</sub>O.<sup>30</sup> As can be also seen that the performance of  
273 Ag(2%)-AgI-Ti was more stable with the increase of temperature than that of AgI-Ti,  
274 indicated the important role of silver.

275

## 276 The analysis of the catalytic mechanism

## 277 The analysis of the mercury combination property

278

279

### Figure 8

280

281 In order to study the mercury combination property of catalysts, the Hg<sup>0</sup>  
282 adsorption and desorption experiments were performed. Figure 8 (a) shows the Hg<sup>0</sup>  
283 breakthrough curves over Ag(2%)-AgI-Ti at various temperatures. As can be seen  
284 from Figure 8 (a), the adsorption ability of Hg<sup>0</sup> was poor above 300 °C, indicated that  
285 Hg<sup>0</sup> was hardly adsorbed at high temperature. Besides, AgI was stable and not

286 decomposed below 400 °C. While the  $\text{Hg}^0$  concentration was reduced slightly at  
287 450 °C, it might be the generated active I, which oxidized  $\text{Hg}^0$ . And the  $\text{Hg}^0$   
288 concentration still high, indicated the amount of active I was less and AgI was still  
289 stable.

290 The Hg-TPD curves for Ag(2%)-AgI-Ti are shown in Figure 8 (b). It can be seen  
291 from Figure 8 (b), some amount of  $\text{Hg}^0$  was desorbed at low temperature, which  
292 might be the decomposition of the silver amalgam. And there were little desorbed  $\text{Hg}^0$   
293 above 300 °C, indicated that  $\text{Hg}^0$  was hardly adsorbed on the surface of catalyst at  
294 high temperature in accordance with the results of Figure 8 (a). The  $\text{Hg}^0$  concentration  
295 reduced at 450 °C, which might be the small amounts of active I was generated.

#### 296 **The analysis of UV/vis spectrum**

297

#### 298 **Figure 9**

299

300 In order to probe on the role of HCl for  $\text{Hg}^0$  oxidation, the reaction by passing  
301 HCl over Ag(2%)-AgI-Ti was recorded by the UV/vis spectrometer. There were no  
302 obvious characteristic peaks for Ag(2%)-AgI-Ti until the concentration of HCl was  
303 5000 ppm, and the results were shown in Figure 9. Figure 9 (a) shows the comparison  
304 of the UV/vis spectrum of various catalysts at 5000 ppm HCl. There was no  
305 characteristic peak for KI-Ti, while an absorption peak of 530 nm can be seen for  
306 AgI-Ti and Ag(2%)-AgI-Ti in Figure 9 (a), which was attributed to  $\text{I}_2$ . This result  
307 suggested that the iodine was formed by adding HCl, and Ag might have a catalytic

308 effect for HCl. Active chlorine could be generated and then oxidized iodine ion to  
309 active iodine. And due to the high concentration of HCl, the amount of active iodine  
310 would be more, so that the reaction was strong to generate I<sub>2</sub>. The peak of I<sub>2</sub> of  
311 Ag(2%)-AgI-Ti was stronger than that of AgI-Ti, which might be due to relatively  
312 high iodine content, indicated that more silver nanoparticles could inhibit the  
313 decomposition of AgI.

314 The UV/vis spectrum of Ag(2%)-AgI-Ti at different temperatures were shown in  
315 Figure 9 (b). The absorption peak intensity at 530 nm (I<sub>2</sub>) increased with the  
316 increasing temperature, suggested that the yield of I<sub>2</sub> increased with increasing  
317 temperature. The number of active Cl might increase with temperature rise, so that the  
318 more amount of active I were generated, meant that Hg<sup>0</sup> would be oxidized more  
319 effectively over catalyst at high temperature.

### 320 **The analysis of ion chromatograms**

321

### 322 **Figure 10**

323

324 To determine reaction products, ion chromatography analysis was employed to  
325 analyze the oxidized mercury products, which were dissolved into the ultrapure water.  
326 Figure 10 shows the ion chromatograms of reaction product. It can be seen from  
327 Figure 10 (b) that there was only one characteristic peak, which can be attributed to  
328 Cl<sup>-</sup>, compared the peak of the standard sample in Figure 10 (a). It was reported iodine  
329 was more reactive than chlorine (two magnitudes) for the removal of Hg<sup>0</sup>,<sup>19</sup> while the

330 peak of I was not found, indicted that the reaction product was not HgI<sub>2</sub>. It may be  
331 that active I combined with Hg<sup>0</sup> in the formation of van der Waals intermediate  
332 molecules, such as Hg-I\*, and then active chlorine converted the intermediate to  
333 HgCl<sub>2</sub>, which was because chlorine was more competitive than iodine to bond with  
334 the oxidized mercury due to the higher redox potential value.<sup>32</sup> Besides, active I  
335 would react with silver to generate AgI, maintaining the stability of iodine.

336 Base on the above results, the possible reaction paths for Hg<sup>0</sup> removal could be  
337 speculated as follows: HCl was adsorbed and activated by silver nanoparticles, and  
338 the generated Cl activated AgI to Ag···I\*. Then Ag···I\* combined with Hg<sup>0</sup> in the  
339 form of Hg-I\*, which reacted with adsorbed Cl on the surface of silver to generate  
340 HgCl<sub>2</sub> and AgI, maintained the stability of Ag(2%)-AgI-Ti catalyst.

341

342 **Figure 11**

343

344 The main reaction process for the Hg<sup>0</sup> oxidation over Ag(2%)-AgI-Ti can be  
345 showed in the Figure 11. As can be seen from Figure 11, iodine in Ag(2%)-AgI-Ti  
346 mainly acted as an accelerant for Hg<sup>0</sup> oxidation by facilitating formation of the  
347 intermediates. And then chlorine can further convert the intermediate to the final  
348 product of HgCl<sub>2</sub>. AgI was recycled in the reaction process, which was beneficial for  
349 the Hg<sup>0</sup> oxidation at a long time.

350 Eqs. (1)–(5) are some of the possible reactions during Hg<sup>0</sup> conversion:

### 356 **The analysis of thermal stability**

357

#### 358 **Figure 12**

359

360 In order to study the thermal stability of catalysts, the thermogravimetric (TG)  
361 analysis was performed. Figure 12 shows the TG curves of various catalysts. As can  
362 be seen from the Figure 12, the weights of AgI-Ti and Ag (2%)-AgI-Ti were declined  
363 below 300 °C, which might be the surface adsorption of water. And the weight of  
364 AgI-Ti was still declined slowly above 300 °C, indicated that some of AgI might be  
365 decomposed to I<sub>2</sub> at high temperature. While the weight of Ag (2%)-AgI-Ti was  
366 reduced little, manifested a very good stability at high temperature, and proved that  
367 Ag could inhibit the decomposition of AgI efficiently.

368

#### 369 **Figure 13**

370

371 To verify the chemical stability of iodide, ion chromatography analysis was used  
372 to detect the amount change of iodide. The experiment process was as follows: a  
373 certain amount of Ag (2%)-AgI-Ti catalyst reacting for 10 h and fresh catalyst were

374 dissolved in sodium thiosulfate solution by ultrasonic dispersion for 24 h, and then the  
375 supernatant of mixture was analyzed. Figure 13 recorded the ion chromatograms of  
376 Ag (2%)-AgI-Ti before and after reaction. The characteristic peak of iodine can be  
377 found in Figure 13 (a) and (b), manifested that iodine still existed on the surface of  
378 catalyst. It revealed the stability of iodine, and proved the conclusion above, which  
379 iodine was accelerant for  $\text{Hg}^0$  oxidation by facilitating formation of the intermediates.  
380 However, the amount of iodine was decreased slightly, and the loss amount was about  
381 20% for 10 h, which might be that the active I on the surface of catalyst was take  
382 away due to the higher space velocity. At actual condition, space velocity could be  
383 adjusted to reduce the loss of iodine, and iodine vapour could be also passed to  
384 catalyst to recover the iodine amount. Furthermore, the characteristic peak of chlorine  
385 was seen in Figure 13. The peak intensity after reaction was stronger than that of  
386 catalyst before reaction to prove that chlorine was adsorbed on the surface of catalyst.

### 387 **Conclusions**

388  $\text{Ag}(2\%)\text{-AgI-TiO}_2$  was an excellent and durable catalyst for  $\text{Hg}^0$  catalytic  
389 oxidation, and can reach 100% with 5 ppm HCl at 350 °C, which was better than  
390 KI-Ti. Adding silver to AgI-TiO<sub>2</sub> can prolong effectively the time of high efficiency.  
391 And 2% Ag content was suitable, for which the  $\text{Hg}^0$  oxidation efficiency was still  
392 above 90% after 10 h. AgI and Ag nanoparticles were loaded on the surface of TiO<sub>2</sub>,  
393 and the addition of silver could inhibit the decomposition of AgI by the analysis of  
394 physical and chemical characterization. The component analysis of  $\text{Hg}^0$  oxidation  
395 indicated that HCl was the major oxidation component and O<sub>2</sub> was necessary, besides,

396 sulfur dioxide inhibited slightly the  $\text{Hg}^0$  oxidization, while nitric oxide can promote  
397 the reaction, and water had little effect on the reaction. The reaction mechanism was  
398 probed by UV/vis spectrums ion chromatography analysis, indicated that HCl was  
399 adsorbed and activated by silver, and the generated Cl activated AgI to  $\text{Ag}\cdots\text{I}^*$ . Then  
400  $\text{Ag}\cdots\text{I}^*$  combined with  $\text{Hg}^0$  in the form of  $\text{Hg-I}^*$ , which reacted with adsorbed Cl on  
401 the surface of silver to generate  $\text{HgCl}_2$  and AgI, maintained the stability of  
402 Ag(2%)-AgI-Ti catalyst. In addition, the thermogravimetric (TG) analysis was  
403 performed, proved that Ag (2%)-AgI-Ti manifested a good stability at high  
404 temperature. Furthermore, the ion chromatograms of Ag (2%)-AgI-Ti before and after  
405 the reaction revealed the chemical stability of AgI-Ti in the presence of Ag.
