Abstract

A small series of norbornane bisether diguanidines have been synthesized and evaluated as antibacterial agents. The key transformation—bisalkylation of norbornane diol **6**—was not successful using Williamson methodology but has been accomplished using Ag_2O mediated alkylation. Further functionalization to incorporate two guanidinium groups gave rise to a series of structurally rigid cationic amphiphiles; several of which (**16d**, **16g** and **16h**) exhibited antibiotic activity. For example, compound **16d** was active against a broad range of bacteria including *Pseudomonas aeruginosa* (MIC = 8 μ g/mL), *Escherichia coli* (MIC = 8 μ g/mL) and methicillin-resistant *Staphylococcus aureus* (MIC = 8 μ g/mL).

Introduction

Antibacterial resistance is now a global medical concern.¹⁻⁴ A decline in the number of pharmaceutical companies pursuing new therapeutics, and the continued misuse of antibiotics has only served to

 $^{^{\#}}$ Institute for Molecular Bioscience, The University of Queensland, Brisbane, Queensland, 4072, Australia.

exacerbate the problem.¹⁻⁵ Many antibacterial agents that target the lipopolysaccharide (LPS) layer of Gram-negative bacteria either possess or adopt an amphiphilic structure.⁶⁻¹⁰ It has also been shown that appropriate functionalization of a rigidified core (such as a calixarene) enables facially amphiphilic compounds to be constructed.⁷⁻¹¹ The bicyclo[2.2.1]heptane (norbornane) scaffold represents one of the most accessible, preorganized frameworks available and has a history of use in many fields of chemistry. Biologically active examples include: naxifylline 1 (an A₁-adenosine receptor antagonist),¹² N⁶-(5,6-epoxynorbornyl)adenonsines (A₁-adenosine receptor agonists)¹³⁻¹⁵ and diguanidine 3, (active against Gram-negative bacteria).¹⁶ In supramolecular chemistry norbornanes have found use in organogel formation,¹⁷ whilst fused polynorbornanes have been successfully employed as scaffolds for both anion recognition,¹⁸⁻²¹ and as ligands for the construction of metal-organic cages.²² In the field of asymmetric synthesis, chiral auxiliaries (such as 2) based on the norbornane framework have also been successfully employed.^{23, 24}

Figure 1: Examples of functionalized norbornanes.

It is known that ethers typically demonstrate better *in vivo* stability than acetals,²⁵ therefore, analogs of antibacterial 3¹⁶ (Figure 1) that followed the general structure 4 (Scheme 1) were considered attractive targets. In order to construct this class of compounds it was envisaged that bisether diacids (5) would be useful building blocks and these could in turn be synthesized from norbornane diol 6 (Scheme 1).

Scheme 1: Access to bisether diguanidine 4 from diol 6.

The direct alkylation of norbornane diol **6** is as yet unreported in the literature, which is presumably because the reaction is troublesome. Indeed, it has been shown that in some cases alkylation of alcohols using typical Williamson protocols gives lower than expected yields, or no desired product.²⁶, Indeed, in circumstances where a stabilized leaving group can be formed the basic conditions employed can lead to an elimination event.^{28, 29} An example of this competitive elimination was described by Hergueta *et al.* (Scheme 2); alkoxide **7**, derived from a norbornane fused to a quinoxaline, undergoes elimination to give a carbanion (**8**) which is stabilized by the aromatic heterocyclic.³⁰

Scheme 2: Ring opening to give stabilized 'benzylic' carbanion as observed by Hergueta et al.³⁰

The use of silver(I) oxide for the transformation of an alcohol to a methyl ether has been known for well over a century.³¹ The Irvine-Purdie method has been used to achieve i) mono-alkylations;³²⁻³⁶ ii) bisalkylation of unhindered diols such as cycohexanediol;³⁷ and iii) per-methylation of carbohydrates such as glucose, galactose and fructose.^{31, 38} Inefficient reaction conditions (e.g. multiple additions of the alkylating agent³⁴ or carrying the reaction out in neat alkylating agent) means the Irvine-Purdie

alkylation is often overlooked in favor of Williamson methodology. To the best of our knowledge, the use of silver(I) oxide for the bisalkylation of eclipsed *syn*-1,2-diols has not been previously described.

Herein, we report a protocol for the bisalkylation of the sterically hindered 1,2-diol 6 using silver(I) oxide and a small excess (4.6 equiv) of suitable alkyl halides. Hydrolysis of the esters gave access to compounds of the general structure 5, which were shown to exist in a sterically congested environment around the two alkyl groups by X-ray crystallography. Subsequent functionalization afforded a series of diguanidines (4, Scheme 1), that were tested against a range of Gram-negative and Gram-positive bacteria (Table 3 and 4).

Results & Discussion

Chemistry

The starting diester diol **6** was synthesized in two steps from dimethyl fumarate. ^{16, 39} The norbornane framework was constructed using either standard Diels–Alder conditions (99%) or by a solvent-free, microwave-assisted approach (2 hours at 150 °C, 98%) similar to that reported by Nencka and coworkers. ³⁹ The *syn*-1,2-diol **6** was synthesized in excellent yields (94%) on multigram scales (up to 4 g), using OsO₄ (0.1 mol%) mediated dihydroxylation of the norbornene using 4-methylmorpholine *N*-oxide (NMO) as a co-oxidant. ^{16, 40} Dihydroxylation using KMnO₄, as detailed by Donohoe, ⁴¹ was also successful, albeit in lower yield (58%) (see Supporting Information for full reaction conditions).

Williamson methodology was initially trialled using **6**, NaH, MeI, at 55 °C (Scheme 2) and after 16 hours the diol had been completely consumed (as determined by TLC analysis). However, examination of the crude product using ${}^{1}H$ NMR spectroscopy showed no signs of the desired bisether **9a**. Instead, a complex mixture (inseparable by column chromatography) was produced. Deprotonation with n-BuLi in THF at -78-0 °C was also trialled but again the reaction was unsuccessful. Given that similar norbornane diols undergo base-induced ring opening to give stabilized anions (Scheme 2), 30 we propose that following deprotonation, a Grob-type fragmentation occurs to give a stabilized enolate (**11**, Scheme 3). 42

Scheme 3: Failed attempt to access bisether 9a and the possible pathway leading to enolate 11.

The Sakai group have described the reduction of esters to the corresponding ethers using Et₃SiH in the presence of catalytic InBr₃.⁴³ Unfortunately, in the current work, after acetylation of diol **6** to form diacetate **20** (63%, see experimental section),⁴¹ reaction with InBr₃ failed to produce the bisether product; instead ¹H NMR analysis indicated that a complex mixture of products had formed.

In light of these failures, attention turned towards the use of Ag₂O.^{32-37, 44, 45} Indeed, when diol **6** was reacted with Ag₂O (1.6 equiv) and MeI (4.6 equiv) in DMF at ambient temperature for 48 hours (Scheme 4), bisether **9a** was isolated in good yield (67%).³³ Saponification of diester **9a** gave the required bisether diacid (**12a**) in 73% yield (Scheme 4). Extended reaction times, adding further portions of MeI throughout the reaction, and heating the reaction (both conventional and microwave irradiation), did not lead to increased yields. Using Ag₂CO₃, AgNO₃, AgBF₄ or AgPF₆ gave none of the desired product with only starting material recovered.

Scheme 4: Synthesis of diacid 12a

To further test the scope of these reaction conditions a range of benzyl halides were used. Using benzyl bromide (Table 1, entry 2), bisether diacid **12b** was attained over two steps (18% using 300 mg

of **6**). Pleasingly, when the reaction was performed on a larger scale (900 mg of **6**), the yield increased to 37%. A Finkelstein approach using NaI did not increase the yield of bisether diacid **12b**. The low yields can be rationalized somewhat by the steric bulk introduced as a result of the first benzylation—the reaction with the second equivalent benzyl halide is considerably inhibited. Indeed, an appreciable amounts of the monoalkylated regioisomer (37%) were isolated along with the desired bisether product **12b**.

Similarly, using 2-methylbenzyl bromide, **12c** was accessed in a 19% yield (Table 1, entry 3), and a reasonable quantity of a monoalkylated intermediate was isolated (39 %). However, despite the modest yields, this protocol provided access to the desired norbornane bisethers—a previously inaccessible family of compounds.

When a range of fluorinated benzyl bromides were used good yields of the desired bisether products were obtained. Following the aforementioned two-step process, **12d** (51%) and **12e** (55%) were accessed in good yields using 4-(trifluoromethyl)benzyl bromide and 3-fluorobenzyl bromide respectively (Table 1, entries 4 and 5). Furthermore, when 4-fluorobenzyl bromide was employed to alkylate diol **6**, and following hydrolysis of the ester groups using NaOH/THF (Table 1, entry 6) diacid **12f** was obtained in moderate yield (25%) over the two steps.

a) Reaction was stirred for 4 days.

Using 3-bromobenzyl bromide and 4-bromobenzyl bromide the synthesis of bisether diacids **12g** and **12h** (24 and 28% over two steps respectively, Table 1, entries 7 and 8) were carried out in the same fashion. Crystals suitable for X-ray diffraction were obtained for bisether diacid **12h** after recrystallization from EtOH/pet. spirits. The resulting structure contained a unit cell comprised of two conformational isomers (as shown in Figure 2). The O···O distance (*ca.* 2.6 Å), clearly illustrates the proximity of the two benzyl groups and their non-symmetric orientation (presumably due to steric constraints).

 $^{^{}b)}$ N.R = no reaction.

c) Yield calculated over two steps.

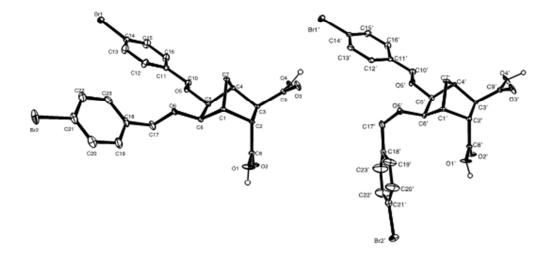

Figure 2: Thermal ellipsoid plot of the two independent molecular confirmations (Ellipsoids at 20% probability level) of compound **12h**.

When allyl bromide was used stirring for 4 days was required to consume all the starting material; subsequent ester hydrolysis gave diacid **12i** in a 25% yield over the two steps (Table 1, entry 9). Unfortunately, reactions with 4-methoxybenzyl chloride and 4-nitrobenzyl bromide (Table 1, entries 10 and 11) failed to give any of the desired product with only minimal consumption of starting material taking place (as evidenced by ¹H NMR analysis of the crude reaction mixture). Also, when 1-iodooctane (Table 1, entry 12) was employed alkylation was unsuccessful.

In six of the alkylation reactions (12b, 12d–12h) transesterification occurred to a small extent (6–12%, as determined using ¹H NMR spectroscopy). This mixed-ester side-product (example 13 from synthesis of 9b, Figure 3) was difficult to separate from the desired dimethyl ester product using column chromatography. The presumption that the more sterically accessible *exo* methyl ester was replaced is based on a previous report by Niwayama and co-workers that illustrated how the *exo* face is less hindered than the *endo* face of related norbornane diesters.⁴⁰ Despite the presence of small amounts of mixed-ester by-products, in each case hydrolysis proceeded smoothly and pure diacids were isolated in every instance.

Figure 3: Representative

structure of proposed mixed-

ester 13 formed during reaction

with BnBr.

With bisethers diacids (**12a–12i**) in hand, functionalization to the required amphiphiles was pursued. Attachment of 2-[2,3-bis(*tert*-butoxycarbonyl)guanidino]ethylamine (**14**)^{47, 48} to the norbornane scaffold was carried out using EDCI and HOBt in either DMF or CHCl₃ using microwave irradiation at 50 °C for 30 minutes to give compounds **15a–15i** in moderate to good yields (26–72%, Table 2). Subsequent deprotection was accomplished using HCl (generated *in situ* from AcCl in MeOH) to give the desired guanidines as the guanidinium chloride salts (**16a–16i**, Table 2).

A balance of both hydrophobicity and hydrophilicity is essential for the antibacterial activity of structural amphiphiles.⁴⁹ In light of this, the calculated LogP (cLogP) values (the log of the octanol/water partition coefficient) were determined for bisether diguanidines (16a–16i) using www.molinspiration.com software (Table 2) and these will be discussed in relation to activity in the following section.

Biological evaluation

The antibacterial activity of these compounds was evaluated against a range of Gram-negative and Gram-positive bacteria, including members of the ESKAPE pathogens;¹ first using the disk diffusion assay to identify active compounds then micro-broth dilution assays to determine minimum inhibitory concentrations (MICs).

Bis-methyl ether **16a** and allyl ether **16i**, did not show any inhibition in disk diffusion studies at 50 μg/disk (Table 3). For the bis-benzyl ether **16b**, a noticeable zone of inhibition (ZOI) was observed (11 mm) against *Pseudomonas aeruginosa*. The inclusion of small substituents to the phenyl rings, such as 2-methyl (**16c**), 3-fluoro (**16e**) and 4-fluoro (**16f**), led to improved activity as shown by ZOI's of 14–16 mm against *P. aeruginosa* and *Klebsiella pneumoniae* (Table 3). Furthermore, appreciable

^{b)} Product was isolated as an HCl salt.

c) Calculated using <u>www.molinspiration.com</u> software.

ZOI's (11–15 mm) were also observed against Gram-positive methicillin-resistant *Staphylococcus aureus* (MRSA). When larger substituents occupied the 4-position of the phenyl ring, inhibition of vancomycin-resistant *Enterococcus faecium* (VRE) was also seen in addition to the aforementioned strains. The 4-(trifluoromethyl)benzyl (**16d**) and 4-bromobenzyl (**16h**) analogs showed ZOI of 18 and 16 mm respectively for VRE (Table 3). The 3-bromobenzyl derivative (**16g**) was active against all pathogens assessed in this study, and was the sole compound to exhibit activity against *Acinetobacter baumannii* (ZOI = 15 mm). Comparison of ZOI between **16g** and **16h** indicates that activity against *A. baumannii*, *K. pneumoniae* and *E. faecium* can be influenced by subtle changes to substituent locations and may have implications in the design of subsequent compounds.

Given the promising results in the disk diffusion screen the substituted benzyl ethers were subjected to a micro-broth dilution assay to quantify MICs (Table 4). When smaller substituents; 2-methyl (16c), 3-fluoro (16e) and 4-fluoro (16f) displaying no MIC \leq 32 µg/mL against any bacterial strain tested (Table 4). When larger substituents were included on the benzyl rings such as 4-(trifluoromethyl)benzyl (16d) MIC values of 32 µg/mL against *A. baumannii*, and 8 µg/mL against each of *P. aeruginosa*, *Escherichia coli* and MRSA (Table 4) were observed. The 3-bromo benzyl-substituted analog (16g) showed a reasonable MIC against both Gram-negative *P. aeruginosa* (32 µg/mL) and Gram-positive MRSA (16 µg/mL) bacterial strains. Furthermore, an MIC of 32 µg/mL was observed for the 4-bromo benzyl-substituted analog (16h) against MRSA (Table 4). A correlation between antibacterial activity and cLogP was apparent with compounds with higher cLogP values (Table 2) showing stronger antibacterial activity.

a) NT = not tested due to lack of activity against the primary gram-positive strain (MRSA ATCC 43300).

Given the encouraging MIC values for compounds **16d** and **16g** against MRSA (Table 4), both compounds were evaluated against seven additional Gram-positive bacterial strains including such *S. aureus* bacterial isolates as multi-resistant methicillin resistant (mMRSA), glycopeptide-intermediate (GISA) and vancomycin-intermediate (VISA), as well as *Streptococcus pneumoniae* and *E. faecalis* (Table 5). The 4-(trifluoromethyl)benzyl bisether (**16d**) was again the most active compound; exhibiting antibacterial activity (MIC = 8–16 μ g/mL) against all eight bacterial strains tested. Furthermore, activity was observed by 3-bromobenzyl bisether (**16g**) against all Gram-positive bacterial strains tested which was highlighted by an MIC of 8 μ g/mL against *S. pneumoniae* (Table 4).

The cell viability (% survival) against human embryonic kidney cells (HEK293) and hepatocellular carcinoma (HepG2) was determined after exposure to compounds **16d** or **16g** at 100 μ M for 24 hours (Table 6). The 4-(trifluoromethyl)benzyl bisether (**16d**) exhibited moderate cytotoxicity with 43 and 56% cell survival observed against HEK293 and HepG2 respectively (Table 5). In the case of bis-3-bromobenzyl ether (**16g**) the cell viability was determined to be 90% and 96% against HEK293 and HepG2 respectively (IC₅₀ < 100 μ M). The cytotoxicity profile for these compounds is acceptable when compared to previously reported antibacterial agents.⁵⁰

Conclusions

The previously inaccessible norbornane bisether diacids 12a-i, were successfully prepared using Ag₂O and a suitable alkyl or benzyl halide as the key step. An X-ray crystal structure of bisether diacid 12h highlighted the sterically crowded environment of the ethers; which presumably hindered the second etherification step and resulted in lower yields. Nevertheless, the protocol presented here provides a viable alternative for the alkylation of congested *syn*-diols or base-sensitive alcohols where typical Williamson ether synthesis conditions fail. Further functionalization of bisether diacids (12a-i) gave a series of bisguanidines as hydrochloride salts (16a-i).

Several of the compounds (16d, 16g and 16h) displayed antibacterial activity, with MIC values as low as 8 μg/mL, against a range of problematic bacterial species including *P. aeruginosa, E. coli, S. pneumonia, E. faecalis* and several strains of *S. aureus*. The results presented here reinforce the notion that the activity of cationic antimicrobial peptides can be mimicked by relatively small, structurally

rigid amphiphiles. Indeed, when compared to other synthetic scaffolds (such as calixarenes) which are used to generate antibacterial amphiphiles,⁹ the low molecular weight of these compounds and their reasonable antibacterial activity make them an attractive class of compounds worthy of further investigation.

General Information. All microwave reactions were conducted using a CEM Discover S-Class Explorer 48 Microwave Reactor, operating on a frequency of 50/60 Hz and continuous irradiation power from 0–300 W. All reactions were performed in sealed reaction vessels. All melting points are uncorrected. All 1 H, 13 C and 19 F NMR spectra were collected on either a 270 MHz FT-NMR spectrometer, a 400 MHz FT-NMR spectrometer, or a 500 MHz FT-NMR spectrometer where indicated. All 2D NMR experiments were performed on a 500 MHz FT-NMR spectrometer. Variable temperature (VT) NMR experiments were performed on a 270 MHz FT-NMR spectrometer. Samples were dissolved in CDCl₃, DMSO- d_6 or CD₃OD where specified with the residual solvent peak used as the internal reference – CDCl₃; 7.26 (1 H) and 77.0 (13 C), DMSO- d_6 ; 2.50 (1 H) and 39.52 (13 C), CD₃OD; 3.31 (1 H) and 49.0 (13 C). 52 Proton spectra are reported as chemical shift δ (ppm) (integral, multiplicity (s = singlet, br s = broad singlet, d = doublet, t = triplet, q = quartet, quin = quintet and m = multiplet), coupling constant (Hz), assignment). Carbon spectra are reported as chemical shift δ (ppm) (integral, multiplicity (d = doublet and q = quartet), coupling constant (Hz)) were appropriate. Fluorine spectra are reported as chemical shift δ (ppm) and were externally referenced using 0.05% α , α , α -trifluorotoluene in CDCl₃; -63.72 (19 F).

High resolution mass spectral data was collected on using a QTOF mass spectrometer (LC-1200 series) under the following conditions: gas temperature (300 °C), nitrogen drying gas (10.0 L min⁻¹),

capillary voltage (3500 V), fragmentor (140 V), and nebuliser (45 psi) in a 80% MeCN in H_2O solvent system. Analyte solutions were prepared in HPLC grade methanol (conc. ~ 1 mg mL⁻¹).

All chemicals and solvents were used as received without further purification unless otherwise stated. Column chromatography was performed on silica gel (230–400 mesh).

General procedure A for the bis-alkylation of diol 6. Anhydrous DMF (2.4 mL) was added to a pre-dried round-bottom flask protected from light, containing diol 6 (3.7 mmol) and Ag_2O (1.6 equiv) at ambient temperature. To the stirring solution was added the appropriate alkylating agent (4.6 equiv) and the reaction was stirred for 48 h before the reaction vessel was cooled to 4 °C (refrigerator) for a further 16 h without agitation. The resulting precipitate was removed by vacuum filtration and washed with EtOAc (15 mL). The filtrate was washed with H_2O (3 × 10 mL), dried (MgSO₄), filtered and concentrated *in vacuo* to afford the crude product which was purified by column chromatography to give the desired bisether.

Dimethyl 5,6-bis(methoxy) bicyclo[2.2.1]heptane-3-*endo*-2-*exo*-dicarboxylate (9a). Compound 9a was prepared from diol 6 (915 mg, 3.74 mmol) and iodomethane (1.1 mL, 17.7 mmol) according to general procedure A and was purified by column chromatography (20% EtOAc in pet. spirits) to give the title compound (682 mg, 67%) as a clear viscous oil; R_f = 0.17 (20% EtOAc in pet. spirits). ¹H NMR (270 MHz, CDCl₃) δ 1.39 (1H, dquin, J = 10.7, 1.6 Hz, H7s), 1.89 (1H, ddd, J = 10.7, 1.6, 1.5 Hz, H7a), 2.64–2.69 (3H, m, H1, H2, H4), 3.20 (1H, dd, J = 5.5, 0.8 Hz, H3), 3.29 (1H, dd, J = 6.0, 1.7 Hz, H5), 3.37 (3H, s, Me), 3.42 (3H, s, Me), 3.46 (1H, dd, J = 6.1, 1.8 Hz, H6), 3.70 (3H, s, Me), 3.72 (3H, s, Me). ¹³C NMR (67.5 MHz, CDCl₃) δ 32.9, 43.3, 44.8, 45.0, 46.4, 52.2, 52.4, 58.7, 58.8, 81.0, 84.1, 173.2, 174.2. General procedure C for the amidation of diacids 12a–i. A microwave vial was charged with the appropriate carboxylic acid, EDCI (3.0 equiv), HOBt (0.1 equiv) and dry DMF and was stirred at ambient temperature for 30 min. Aminoethylguanidine 14 (3.0 equiv) was then added and the reaction was irradiated to 50 °C for 30 min. The resulting homogenous clear mixture was diluted with EtOAc (15 mL), washed with H_2O (3 × 8 mL), brine (8 mL), dried (MgSO₄), filtered, and concentrated *in vacuo* to afford a solid that was purified by column chromatography (as specified below) to give the title compound.

Crystallography. Intensity data were collected with an CCD diffractometer using Cu- Kα radiation, the temperature during data collection was maintained at 130.0(1) using an Oxford Cryosystems cooling device. The structure was solved by direct methods and difference Fourier synthesis.⁵³ Thermal ellipsoid plots were generated using the program ORTEP-3⁵⁴ integrated within the WINGX⁵⁵ suite of programs. Disordered solvent, assumed to be ethanol was removed using the Squeeze procedure.⁵⁶

Disk Diffusion – **Zone of Inhibition assay**. A stock solution of 10 mg/mL was made for each compound under observation using DMSO as a solvent. Each of these stock solutions was then diluted by a factor of 1:2 to bring the concentration to 5 mg/mL. The diluted solutions were then filter-sterilized using a 0.2- μ m nylon filter, and 10 μ L of the 5 mg/mL stock was pipetted onto a blank

disk (i.e. 50 μ g/disk; Oxoid Limited, Hampshire, UK). All bacterial isolates were matched to a 0.5 McFarland standard (in 0.9% NaCl) before they were swabbed onto nutrient agar. The controls used were a 10 μ g colistin disk (Oxoid), 10 μ L of DMSO and a plate swabbed with saline from the dispenser used.

Minimum Inhibitory Concentration (MIC) determination. Bacteria were obtained from American Type Culture Collection (ATCC; Manassas, VA, USA) as listed in Table S2 (see ESI). Bacteria were cultured in Nutrient broth (NB; Bacto Laboratories, catalog No. 234000) or Muller-Hinton broth (MHB; Bacto Laboratories, catalog No. 211443) at 37 °C overnight with shaking (~180 RPM). A sample of each culture was diluted 50-fold in fresh MHB and incubated at 37 °C for 1.5–3 h with shaking (~180 RPM). Compound stock solutions were prepared as 10 mg/mL in DMSO and colistin was dissolved in milli-Q water at 5.12 mg/mL. The compounds, at twice the final desired concentration, were serially diluted 2-fold across the wells of 96–well plates (Non-Binding Surface, Corning, catalog No. 3641). Mid-log phase bacterial cultures (after 1.5–3 h incubation) were diluted to a final concentration of 5 × 10⁵ colony forming units (CFU)/mL, and 50 μL was added to each well giving a final compound concentration range of 32 μg/mL to 0.015 μg/mL (DMSO ≤ 1%). MICs were determined visually after 20 h of incubation at 37 °C, with the MIC defined as the lowest compound concentration at which no bacterial growth was visible.

Cytotoxicity evaluation. HEK293 (ATCC CRL-1573) and HepG2 (ATCC HB-8065) cells were seeded as 3000 cells per well in a 384-well plate in in DMEM medium (GIBCO-Invitrogen #11995-073), in which 10% of FBS was added. Cells were incubated for 24 h at 37 °C, 5% CO₂ to allow cells to attach to the plates. A concentration series of compounds was then added into each well. The cells were incubated with the compounds for 24 h at 37 °C, 5% CO₂. After the incubation, 10 μ M resazurin (dissolved in PBS) was added to each well. The plates were then incubated for 2 h at 37 °C, 5% CO₂. The fluorescence intensity was read using Polarstar Omega with excitation/emission 560/590. The data was analysed by Prism software. Results are presented as the average percentage of control \pm SD

for each set of duplicate wells using the following equation: Percentage Viability = (FITEST – $FI_{Negative}/FI_{UNTREATED} - FI_{Negative}) \times 100$.
