Graphical Abstract

Model peptides containing the 3-sulfanyl-norbornene amino acid, a conformationally constrained cysteine analogue effective inducer of 310-helix secondary structures

Clerici, Francesca; Ruffoni, Alessandro; Contini, Alessandro; Soave, Raffaella; Lo Presti, Leonardo; Esposto, Irene; nava, donatella; Pellegrino, Sara; Gelmi, Maria; maffucci, irene

Two model peptides containing the unnatural cysteine mimic, 3-benzylsulfanylnorbornene amino acid (NRB) was prepared. Theoretical calculations, spectroscopic and X-Ray analyses confirmed that both NRB enantiomers possess a strong strong right-handed helicogenic effect in the presence of L-Alanine.

Model peptides containing the 3-sulfanyl-norbornene amino acid, a conformationally constrained cysteine analogue effective inducer of 3_{10} -helix secondary structures[†]

Alessandro Ruffoni,^a* Alessandro Contini,^a Raffaella Soave,^b Leonardo Lo Presti, ^c Irene Esposto,^a Irene Maffucci,^a Donatella Nava,^a Sara Pellegrino,^a Maria Luisa Gelmi,^a Francesca Clerici ^a*

Abstract. The properties of the constrained tetrasubstituted 3-sulfanylnorbornene amino acid (NRB), when inserted in Ala-Aib model peptides, were extensively studied. The conformational behaviour of these models was evaluated by theoretical calculations, spectroscopic analyses and by X-ray crystallography. Taken together, our data confirm that both (R, R, R, S)- and (S, S, R)-NRB enantiomers possess a strong helicogenic effect when inserted in short Ala-Aib sequences, suggesting that the rigid norbornane core plays a positive effect on the ability to stabilize helical secondary structures. These information will be essential for future applications in the rational design of conformationally stable peptides targeted on protein-protein interaction (PPI) surfaces.

Introduction

Protein-protein interactions (PPI) represent a central event in biological pathways and the possibility to modulate such interactions is considered of great importance.¹ Several efforts were devoted to discover new small drug-like molecules acting as modulators of PPI, but sometimes providing unsatisfactory results.² Recent strategies are focused on the use of *ad hoc* designed natural peptides,³ which, however, often have a low stability, bad pharmacokinetics and an unstable conformation.⁴ The exploitation of non-natural amino acids (AAs) in peptide synthesis is very useful to overcome these problems. Peptidomimetic sequences⁵ are inherently resistant to proteases and peptidases and can fold into well-ordered secondary structure consisting of helices, turns and sheets.⁶

Such stabilized secondary structures might be crucial to enhance the activity and selectivity of interaction with a specific biological target. In particular, C α -tetrasubstituted α -amino acids (CTAAs) were used to stabilize bioactive helical peptides.⁷

In our laboratory, synthetic procedures for the preparation of several constrained CTAAs^{6b, 8-11} were developed. Some of these were successfully used for the preparation of short peptides, which fold into stable helical structures. Clearly, the ability of a new amino acid to induce a defined secondary structure must be proved by experimental data. Moreover, the stereochemistry of the new AA is of fundamental importance: depending on the enantiomer chosen, a different conformational stability of the resulting isomeric peptide could be expected. ^{6b}

In the last few years interest toward Rac1 protein, whose activation is mediated by Tiam1, has increased for its role in cancer and cardiovascular diseases.¹² In a recent article we described the design and synthesis of a new class of small molecules acting as Rac1-Tiam1 PPI inhibitors.¹³ These compounds, even if of great interest, showed, as other inhibitors reported so far, a potency too low for a potential use in therapy (low μ M range).¹⁴

Preliminary studies performed in our laboratory identified a peptide sequence containing hot and warm spots in the 13 residue long helix of Tiam1, CR3 (I1187-L1199); however, this portion cannot be used as a stand-alone peptide inhibitor, since it is predicted to be disordered.¹⁵ Taking into account the above considerations, the introduction into the peptide sequence of one or more CTAAs would

result in a helical structured more stable peptide. According to recent studies of our group,¹⁶ we chose the 3-benzylsulfanyl amino ester **1** containing the norbornene amino acid (NRB) as a CTAA. First of all we planned the preparation of model pentapeptides Ac-Ala-NRB-Ala-Aib-Ala-NH₂ of general formula **2** (Figure 1).by using both enantiomers of NRB. The conformational behavior of these models and the ability of the two different enantiomers of NRB to induce a defined secondary structure was evaluated by theoretical calculation, spectroscopic analyses, and by X-ray crystallography. These information, besides being of importance for developing new peptidomimetic inhibitors of Rac1-Tiam1 PPI, might lay the ground for future applications in the rational design of other new bioactive peptidomimetics.

Results and discussion

The synthesis of 1 (R = Et) previously described by us,¹⁰ was scaled up to 1.5 grams in order to assure the availability of a congruous amount of starting NRB.

For the preparation of pentapeptides 2 several strategies were tested. Firstly, we planned to use the procedure depicted in Scheme 1, whose key step consists in coupling the diastereoisomeric dipeptides Ac-Ala-NRB-OH (3) with the TFA salt of the tripeptide H-Ala-Aib-Ala-NH₂ (4), synthesized by solid phase synthesis.^{6b}

Accordingly, **1** was submitted to hydrolysis obtaining the fast conversion of the ester into acid in high yield but, as already observed in similar cases¹⁰, together with the addition of HCl to the double bond. Operating in basic condition resulted in very slow reaction, low yield and purification difficulties. To overcome this problem the double bond of **1** was reduced providing **5** (Scheme 2), which was reacted with FmocAlaF as both reagent and resolving agent.¹⁷ Unfortunately, an inseparable mixture of the two expected diastereoisomers was obtained. Fmoc deprotection (piperidine, DMF) afforded the two diastereoisomers **6a** and **6b** (95% overall yield), which were partially separated by simple flash chromatography.

The two compounds were analysed to ascertain their correct structure, but very little differences were observed in protons chemical shifts (1H NMR, see experimental), the main difference being the methylenic protons of ester function (see SI). A confirmation of the correct structure and stereochemistry came from X-Ray analyses. Suitable crystals were obtained only for one of the two diastereoisomers (6a: AcOEt:CHCl₃ 1:1; RT; 24h). Finally, acetylation of 6a and 6b followed by hydrolysis of the ethyl esters provided 7a and 7b. Unfortunately, the hydrolysis led to racemization of the alanine stereocenter or to a partial cleavage of amides bond despite to numerous reaction conditions tested (NaOH,

amides bond despite to numerous reaction conditions tested (NaOH, KOH, LiOH, or HCl 3N, 6N, 37%). However, we tried to couple the crude containing **7a** with the tripeptide H-Ala-Aib-Ala-NH₂ (**4**) operating in standard conditions (EDC 1.1eq., HOAt 1.1eq., DCM, 0° C), but we obtained an inseparable mixture.

The main drawbacks of the synthetic way described above were the limited scalability of the known solid phase synthesis of the tripeptide H-Ala-Aib-Ala-NH₂ (4)^{6b} and the racemization events during the hydrolytic procedures. Consequently, first of all we set up a linear Boc chemistry solution strategy that allowed us to prepare the tripeptide 4 as a free amine in 50% overall yield on a gram scale (Scheme 3). The process consisted in the coupling between H-Ala-NH₂ (9) or the dipeptide H-Aib-Ala-NH₂ (11) with the Boc-protected AA 8 and, respectively, 12 in standard conditions (see Scheme 3). The coupling afforded respectively the dipeptide Boc-Ala-NH₂ (10) and the tripeptide Boc-Ala-Aib-Ala-NH₂ (13).

Scheme 3. Gram scale synthesis of the tripeptide 4

The Boc deprotection of **10** was, as usual, realized by treatment with TFA/DCM. On the other hand the deprotection of **13**, affording the desired compound **4**, was obtained by microwave (20+20 min, 150° C) mediated thermal decomposition of Boc protection.¹⁸

In such way we avoided the formation of the corresponding TFA salt, negatively affecting the key coupling with the Boc protected NRB **15**.

Having in hand a good protocol for the preparation of compound 4, we reconsidered the use of AA 1 and a different strategy was set up to obtain peptides 2.

First, the Boc-protected NRB **15** was prepared in good yield on gram scale according to standard protocols through the reaction of **1** with Boc anhydride, giving **14**, followed by hydrolysis of the ester function in basic conditions (KOH 3M in MeOH, Scheme 4). Compound **15** was coupled with the tripeptide **4** in the conditions reported in Scheme 4, affording the two expected diastereoisomeric tetrapeptides **16a** and **16b** (yield 75%) that were successfully separated by flash chromatography. The following microwave assisted Boc deprotection afforded compounds **17a** (82%) and **17b** (88%) without racemization.

Peptides **17a** and **17b** were then reacted with Ac-Ala-OH in different

conditions. (Scheme 5) To optimize the yields and to minimize racemization, several synthetic protocols were tested which are reported, together with yields and percentage of racemization, in Table 1, starting from 17a (entries 1-5) and 17b (entries 6-10), respectively. The best conditions to obtain compound 2a from 17a resulted in using classic coupling condensation conditions (HOAt

1.1 eq., EDC 1.1 eq., DIPEA 2.2 eq., DCM, entry 1). In this way, pure compound **2a** was obtained after HPLC purification (40%).

In the case of **17b** partially satisfactory results were obtained by using EEDQ (entry 7) as the condensing agent in THF as the solvent. Racemization process was avoided but the yield was still low.

It is well known that MWs are able to promote unfolding of peptides and this effect is exploited in solid phase peptide synthesizers, thus allowing a general increase of yields. Nevertheless, to our knowledge, few examples are present in the literature concerning the use of MW in solution peptide synthesis,¹⁹ and only one example employing an unnatural AA (Aib).²⁰ As a result, a sample containing **17b**, Ac-Ala-OH and EEDQ in THF was irradiated for 30' at the lowest temperature reachable by a conventional compressed aircooled MW reactor (80 Watt) (Table 1, Entry 6). After 30 minutes, the solution was by cooled and peptide **2b** directly precipitated in pure form in 60% yield.

Conformational Study

X-ray diffraction.

Crystal structure data have been deposited at the Cambridge Crystallographic Data Centre, and allocated the deposition numbers CCDC 989313 (compound **6a**) and CCDC 989314 (compound **2b**). Single crystals of **6a** were grown by slow evaporation from a mixture 1:1 of ethyl acetoacetate and chloroform, while those of compound **2b** by slow evaporation from a solution of acetonitrile.

X-ray analysis of 6a: the analysis allowed the determination of the absolute stereochemistry of the five asymmetric carbons (Figure 2) and evidenced hydrogen bonding interactions (SI pp. S56)

The Ala group undergoes a significant apparent thermal motion, which could imply some kind of disorder. As for the crystal packing (SI pp. S56), the system forms *zig-zag* ribbons of head-to-tail hydrogen bonded (HB) molecules parallel to the *a* axis. The only relevant HB contact involves one H atom belonging to the terminal amine group and the amidic oxygen of an opposing Ala unit. Another possible HB donor is the amidic N–H group, which is actually involved in an intramolecular short contact with the sulfur atom (Figure 2, Table 2)

X-Ray analyses of 2b: the analysis confirmed the absolute stereochemistry of NRB and that no racemization occurred during the whole synthetic process. Interestingly, the asymmetric unit is composed of two molecules ($2b^i$ and $2b^{ii}$ hereinafter) as shown in Figures 3a and 3b. The φ and ψ dihedrals of both the conformations present in the crystal cell were close to the ideal values of a 3_{10} -helix ($\varphi = -49$; $\psi = -26$) with a right handed screw sense, as shown in Table 3.

^a**2b**ⁱ and **2b**ⁱⁱ are the two different conformers of peptide **2b** in the crystal cell. b Dihedral values obtained by REMD simulation, as described in the computational analysis section.

Four consecutive intramolecular short contacts occur in both conformers. They involve the NH protons of CONH₂, Ala(5)NH, Aib(4)NH and Ala(3)NH, as listed together with their geometrical parameters in Table 4. Three of them are common in the two conformers, i.e. they involve the same NH groups as donors (N1, N2 and N4) and the same O atoms as acceptors (O5, O3 and O1). Again in both the conformers, out of the two NH protons of the CONH₂ group, only one is involved in a short intramolecular contact: while in conformer $\mathbf{2b}^i$ the interaction arises between the N6A-HN6A2 group and atom O1A, in 2bⁱⁱ it involves the N6B-HN6B2 and atom O2B. The pattern of H bonds underlined by the crystal structure completely reflects the typical distribution i-i+3 of 3₁₀-helix for the conformer $2b^{ii}$. Regarding $2b^{i}$ the 3_{10} -helix H bond distribution is respected except for the CONH2 proton that present a i-i+4 hydrogen bond interaction typical of α -helix. Such deviation of $2b^i$ from ideal values for the terminal Ala(5) is also detectable in the angles $\psi 4$ and ϕ 4 that differ much more from ideal 3₁₀-helix than in **2b**ⁱⁱ.

Weak hydrogen interactions (i.e. C-H···O, C-H···N and C-H··· π)²² have been found to be critical in stabilizing different molecular geometries²³⁻²⁸. In a previous work, our computational model underlined that the formation of an intra-residue C-H···O hydrogen bond was responsible of the helix stabilization exerted by an unsubstituted norbornene AA included in the same peptide model herein described.¹⁶ In both **2b**ⁱ and **2b**ⁱⁱ, it can be noticed the presence of a C-H···O interaction between H22A and O1A, corresponding to that observed in the computational analysis of the unsubstituted norbornene, but also an additional interaction between H8A and O1A (Table 4), which might further enhance the NRB helix stabilizing power thanks to the correct orientation of ψ 2.

Figure 3b. Stereoview of the molecular structure of compound **2b** in the crystal state at 150 K, showing 50% probability displacement ellipsoids. Only the molecule numbered as $2b^{ii}$ in the asymmetric unit is shown.

Moreover, to our knowledge, only few example of crystal structures of pentapeptides containing both proteogenic and non proteogenic AAs have been reported so far containing at least two non proteogenic AAs.²¹ The obtainment of a well-defined crystal structure for a pentapeptide containing only two non-proteogenic AAs, Aib and NRB, suggests that the pentapeptide is strongly structured.

NMR Spectroscopy

Both peptides 2a and 2b were subjected to NMR conformational analysis. Experiments were performed in both cases in CD₃CN (20 mM) in order to avoid the hydrophobic collapse typical of chlorinated solvent and simulate as much as possible a polar medium. Homonuclear and Heteronuclear 2D NMR experiments permitted an overall assignment of 2a and 2b proton and carbon resonances (See SI, pp. S4-S12, COSY, HSQC, HMBC spectra)

NOESY experiments on compound 2b. NOESY spectra allowed the identification of all sequential short range NH_{i} - NH_{i+1} cross peaks in the amide region (SI, pg. S8), that are diagnostic of helical conformation.²⁹

The analysis of $C^{\alpha(\beta)}$ H-NH enabled the discrimination between the 3_{10} -helix and the α -helix structures. No C^{α} H_i-NH_{i+4} cross-peaks inherent of α -helix were detectable in the NOESY spectra, but many diagnostic C^{α} H_i-NH_{i+3} and C^{α} H_i-NH_{i+2} medium range cross-peak signals typical of 3_{10} -helix were present. An inspection of the fingerprint area of NOESY spectrum revealed three C^{α} H_i-NH_{i+3} [Ala(1)H^{α}-Aib(4)NH, Ala(3)H^{α}-CONH₂ (Figure 4) and AcMe-Ala(3)NH, (Figure 5)], and two C^{α} H_i-NH_{i+2} [Ala(1)H^{α}-Ala(3)NH (Figure 4), AcMe-NRB(2)NH (Figure 5)] supporting the hypothesis of a 3_{10} -helix structure.

Figure 4. C^αH-NH cross peaks in the NOESY spectrum (τm 500ms, BBI probe, 300 K, 500 MHz) of peptide **2b** in CD₃CN (20 mM). Sequential short range C^αHi-NHi+1 signals diagnostic for structured peptide. Medium range C^αHi-NHi+3 and C^αHi-NHi+2 signals typical of 3₁₀-helix (α red box, β green box).

Figure 5. C^βH-NH cross peaks in the NOESY spectrum (τm 500ms, BBI probe, 300 K, 500 MHz) of peptide **2b** in CD₃CN (20 mM). Medium range C^βHi NHi+3 and C^βHi-NHi+2 diagnostic for helical structure (α red box, β green box).

Also medium and short range signals $C^{\beta}H_{i}$ - NH_{i+3} (Ala(1)Me-Aib(4)NH, Ala(3)Me-CONH₂ and Aib(4)Me-Ala(1)NH, Figure 6) and $C^{\beta}H_{i}$ - NH_{i+2} [Ala(5)Me-Ala(3)NH, Aib(4)Me-CONH₂ (Figure 5) and NRB(2)H3-Aib(4)NH (Figure 4)] confirmed the initial hypothesis.

Finally, a high degree of structuration of peptide **2b** could be inferred by the presence of an unusual and intense long range crosspeak between the H3 proton of the norbornene scaffold and the Me groups of Ala(5) and Ala(1) α -Aib(4)Me as shown in Figure 6.

Figure 6. $^{\alpha}$ H-Me of the NOESY spectrum (tm 5000 ms, BBI probe, 300 K, 500 MHz) of peptide 2b in CD_3CN (20 mM).

NOESY experiments on compound 2a. Despite the overlap of two H^{α} and two NH amide protons which complicated the interpretation of NMR data, valuable structural information were obtained. Using standard sample conditions in CD₃CN (20 mM) all sequential short range NH_i-NH_{i+1} interactions were visible (SI, pg. S13) except the interaction between Ala(5)NH-CONH₂, obscured by

the phase of diagonal peaks. By acquiring the NOESY spectrum at lower concentration (8 mM), we identified the entire sequence confirming an helical construct for 2a (SI, pg. S13).²³

Moreover, 3D structural information present in the $C^{\alpha(\beta)}H$ -NH region of the NOESY spectrum of **2a** were enough to confirm the preference of a 3₁₀-helix over a α -helix. Detectable interactions $C^{\alpha(\beta)}H_i$ -NH_{i+2} (Ala(1)H^{α}-Ala(3)NH, NRB(2)H^{β}-Aib(4)NH, AibMe-CONH₂ and AcMe-NRB(2)NH) and $C^{\alpha}H_i$ -NH_{i+3} (Ala(1)H^{α}-Aib(4)NH, NRB(2)H^{β}-Ala(5)NH and AcMe-Ala(3)NH) are shown in Figures 7 and 8. In conclusion, the absence of C ^{$\alpha(\beta)}H_i$ -NH_{i+4} cross peaks in the NOE spectrum suggests that both enantiomers of **1**, once inserted in the model peptides **2a** and **2b**, stabilize a 3₁₀-helical structure.</sup>

Figure 7. C^αH-NH cross peaks in the NOESY spectrum (τm 500 ms, BBI probe, 300 K, 500 MHz) of peptide **2a** in CD₃CN (20 mM). Sequential short range C^αHi-NHi+1 signals diagnostic for structured peptide. Medium range Cα(β)Hi-NHi+3 and C^{α(β)}Hi-NHi+2 signals typical of 3₁₀-helix (α red box, β green box).

Figure 8. C^βH-NH of the NOESY spectrum (τm \mathbb{Z} 500ms, BBI probe, 300K, 500MHz) of peptide **2a** in CD₃CN (20mM).Sequential short range CαHi-NHi+1 signals diagnostic for structured peptide. Medium range C^{α(β)} Hi-NHi+3 and C^{α(β)} Hi-NHi+2 signals typical of 3₁₀-helix (α red box, β green box).

VT-NMR and DMSO_{d6} titration. To confirm the presence of a 3_{10} -helical structure, the H-bond network within the peptide

backbone was analyzed by measuring the temperature coefficient of the chemical shifts ($\Delta\delta(\text{NH})/\Delta T$) for each NH of **2a** and **2b**, as well as the variation of chemical shift by DMSO- d_6 titration ($\Delta\delta$ / Δ DMSO- d_6 v/v).

Three stable consecutive H-bonds, involving NH protons of CONH₂, Ala(5)NH and Aib(4)NH, are detected (Figures 9 and 10) demonstrating, according to our proposal, a full helical construct for both peptides **2a** and **2b**. In peptide **2b**, Ala(3)NH also presents very low $\Delta\delta$ values, supporting the presence of a further intramolecular H-bond which is only compatible with 3₁₀-helical structure. Indeed, the N terminal Ala(1)NH coefficient and, as might be expected, one NH proton of CONH₂ group are near to the limit of -4.5 ppbK⁻¹ that points out the not H-bonded NH protons. The DMSO-*d*₆ titration

reflects the result of VT-NMR, since no variation of chemical shift are detectable for CONH₂, Ala(5)NH and Aib(4)NH, as shown in Figure 10. In both experiments related to **2a** and **2b**, the NRB(2)NH amide proton showed an unexpected stability. Considering that NH solvent exposition influences, to varying degrees, both the variabletemperature analysis and DMSO- d_6 titration, such result could be a false positive ascribed to the solvent exclusion sphere generated by the norbornene scaffold and the benzylsulfanyl group, as supported by NOESY spectra. The same hypothesis could also explain the low $\Delta\delta$ observed for Ala(3)NH in **2a**, which disagrees with the extremely stable trend found in DMSO- d_6 titration.

Non-magnetic equivalence. Lastly, a proof of an high content of a preferred helical conformation could be deduced from the anisochronicity of the ¹³C NMR signals of the diastereotopic methyl groups in Aib(4). Considering that neighboring chiral residues could not induce a non-magnetic equivalence (NME) higher than 0.5 ppm, the large NME with value of 3.07 ppm (26.26-23.19 ppm, SI, pg. S14) for peptide **2b** and 3.88 ppm (26.60-22.72 ppm, SI, pg. S15) for peptide **2a** could only derive from the presence of a stable helical secondary structure.³⁰

Computational analysis.

In order to gain a deeper knowledge about the folding preferences of peptides 2a and 2b, based on the two enantiomers (*R*,*R*,*R*,*S*) and

(*S*,*S*,*R*)-NRB, we planned a molecular dynamics (MD) study of the two pentapeptides models using the Amber12 package.³¹ The replica exchange molecular dynamics (REMD) method,³² a generalizedensemble algorithm performing random walks in energy space, thus helping a system to escape from local energy traps, has been successfully adopted in secondary structure predictions due to its improved sampling capabilities over standard MD runs. REMD simulations (12 replicas with temperatures exponentially spaced between 260 and 660 K) were then performed by starting from extended conformations and by using a protocol previously optimized for similar questions.^{6b} The peptide was simulated for 50 ns, and analyses were performed on the final 25 ns of the 308.5 K trajectory, being this temperature the closest one to experimental conditions. Trajectories were analyzed in terms of H-bonds, secondary structure and cluster analyses (Tables 5-7). Although the adopted simulation protocol already proved to be successful in predicting the structure of similar peptide models containing CTAAs,^{6b} the comparison of the representative structure obtained from a cluster analysis of the REMD trajectory of peptide **2b** with the corresponding crystal structure further supported the reliability of the method adopted here (Figure 11 and Table 3)

Figure 11. Comparison between the X-ray structure of 2b (carbon colored in green) and the representative geometry of the most populated cluster coming from the cluster analysis of the 308.5 K REMD trajectory of 2b (RMSD (C α) = 1.1 Å)

As we can see from H-bond analysis (Table 5), both peptides **2a** and **2b** are characterized by two i+3 \rightarrow i H-bonds, which are typical of 3₁₀-helices, between residues 1-4 (Ala(1) and Aib(4), respectively) and 2-5 (NRB(2) and Ala(5), respectively). Although the overall H-bond occupancy in **2a** and **2b** is comparable, it can be observed that the most stable H-bond is found between Ala(1) and Aib(4) (occupancy = 68.4%) in **2a**, while in **2b** it is between NRB(2) and Ala(5). In both structures, the third observed H-bond is of the i+4 \rightarrow i type, indicative of an α -helix, and has an occupancy of 2.5 and 1.6%, respectively, suggesting that this secondary structure is only occasionally sampled.

Table 5. H	I-bond ^a	analysis	of the	last	25 n	s of	` the	308.5	K	ff99SB	REMD
trajectory for	or pepti	des 2a ar	nd 2b.								

	2a (<i>R</i> , <i>R</i> , <i>R</i> , <i>S</i>)-NRB	2b (<i>S</i> , <i>S</i> , <i>S</i> , <i>R</i>)-NRB
H-bonds	Occupancy	
Ala(1) C=O…HN Aib(4)	68.4%	46.4%
Ala(1) C=O…HN Ala(5)	2.5%	1.6%
NRB(2) C=O···HN Ala(5)	54.2%	73.4%

^a Only H-bonds with an occupancy > 1% are reported. H-bonds involving the capping Ac and NHMe groups are not reported.

The secondary structure analysis (Table 6), based on the DSSP method,³³ while confirming the results of H-bond analysis, provided per-residue information on the secondary structure. Interestingly, as also observed from the H-bond analysis, (R,R,R,S)-NRB seems to propagate the 3₁₀-helix stabilization toward the N-terminus, while the (S,S,S,R)-NRB enantiomer seems to exert its stabilizing effect mostly toward the C-terminus of the model peptide.

[a] Results for the two most populated clusters, covering above 90% of the total population, are reported. Populations (%) of the remaining 3 clusters are: 0.3, 0.3, and 0.0 for **2a**, 6.0, 1.9, 0.8 for **2b**. Geometries of the most representative structures of **2a** and **2b** are depicted in Figures reported in the SI, pp. S52 and S53, respectively.

Further confirmation came from the cluster analysis of the REMD trajectories. As reported in Table 7, the first three most populated cluster represent over the 95% of the total population for both 2a and **2b** peptides. Concerning **2a**, φ and ψ values for the representative structure of cluster #1 (pop. = 79.1%) fall within the helix region, with a quite significant deviation only for the φ_4 dihedral angle of the C-terminal Ala(5). A quite wide ψ_2 dihedral angle is also observed (-57.7 deg.), possibly due to the steric hindrance between the -SBn group of NRB(2) and the -CH₃ of Ala(3) (C3'HH-CH₂distance = 2.5 Å; (see Figure reported in the SI, pg S52)Cluster #2, which is significantly populated (pop. = 20.3%), corresponds to a partially folded structure where φ and ψ values for residues 1-3 fit with a right-handed helix, while Aib(4) φ and ψ dihedrals angles fall in the left-handed helix region, analogously to what observed for other CTAAs.^{7b,9} Clusters #3-5 are barely populated (pop. = 0.3, 0.3and 0.0%, respectively) and their representative structures correspond to unordered conformations. Concerning peptide 2b, cluster #1 (pop. = 82.6%) also corresponds to a well ordered 3_{10} helix and, differently from what observed for 2a, the ψ_2 dihedral angles also fits with such a secondary structure. Indeed, due to the opposite stereochemical configuration, the -SBn group of NRB(2) points away from the helix core (Figures 8 and pg S53, SI). Cluster #2. 8.7% of the total population, represents a folding intermediate with most of the φ and ψ dihedral angles falling in the left-handed helix region, while, interestingly, the representative structure of cluster #3 (pop. = 6.0%), corresponds to a completely folded lefthanded helix (Figure S6, Page S55 S.I.), a secondary structure not observed for 2a (Figure reported in the SI, pg S52). Clusters #4 and #5, overall representing 2.7% of the total population, correspond to an unfolded conformation and a left-handed folding intermediate, respectively. Taken together, in agreement with the experimental

result, the above data confirm that both (R,R,R,S)- and (S,S,S,R)-NRB enantiomers possess a strong helicogenic effect when inserted in short Ala-Aib sequences. In our previous work on the Azn CTAA^{6b} only the (R)-enantiomer was shown to be helicogenic within Ala-Aib pentapeptides, suggesting that the rigid norbornane core plays a positive effect on the ability to induce helical secondary structures. However, considering the results from REMD simulations and cluster analyses, it cannot be excluded that the (S,S,S,R)-NRB enantiomer could also behave as a powerful inducer of left-handed helices if coupled with *D*-AAs and/or achiral CTAAs such as Aib.

Conclusions

We have prepared two model pentapeptides 2a and 2b containing the unnatural cysteine mimic, 3-benzylsulfanylnorbornene amino acid (NRB) in a short chain sequence of Ala/Aib. All the synthetic steps were optimized allowing the preparation of a satisfactory amount of the pentapeptides containing steric congested NRB in good yields with a new MW assisted protocol. The presence of the C5-C6 double bond in the norbornene scaffold opens the way to further functionalization and/or reduction directly on the model peptides. The conformation of the model compounds 2a and 2b was studied by both theoretical calculation and spectroscopic analyses and confirmed by X-Ray analysis. Interestingly, all the collected data confirm that both NRB enantiomers possess a strong right-handed helicogenic effect in the presence of L-Alanine, as previously observed for the unsubstituted norbornene AA, where this peculiar effect was explained by the network of weak hydrogen interactions stabilized by the rigid norbornane core.¹⁶ Moreover crystal structure gave a proof of the stabilization mechanism of such core. These results open the way for the design and the synthesis of stable peptides able to modulate pharmacologically relevant PPIs.

(1R*,2R*,3R*,4S*)-3-(benzylthio)-2-((tert-butoxycarbonyl)amino) bicyclo[2.2.1]hept-5-ene-2-carboxylic acid (15). To solution of compound 14 in dry DCM/MeOH (9:1, 0.1 M) in a sealed reactor, a solution of KOH in MeOH 6 M (20 eq.) was added and let to react at 70°C for 8 h. The reaction is monitored bt Tlc (EtOAc: hexane, 1 : 2; detected by ninhydrin and UV light). Upon the consupption of starting material the reaction mixture was filtered, the organic solvent was evaporated and the crude was dissolved in HCl 1M at 0°C until pH=2. Then it was extracted 3 times in EtOAc. The combined organic phases was dried over Na₂SO₄ and the solvent was evaporated at reduced pressure affording 15 in pure form as colorless wax (88% yield). The reaction was performed with comparable yield from 0.1g to 1.0 g. ¹H-NMR δ (200 MHz, CDCl₃): 7.37-7.23 (5H, m), 6.25-6.20 (1H, m), 6.14 (1H, s), 6.02-6.00 (1H, m), 4.16 (1H, d, *J* = 3.1 Hz), 3.74 (1H, s), 3.67 (2H, s), 3.02 (1H, s), 1.69 (1H, d, *J* = 9.6 Hz), 1.54 (1H, d, J = 9.8 Hz), 1.47 (9H, s). ¹³C-NMR δ (50 MHz, CDCl₃): 174.61, 158.59, 138.01, 137.26, 135.74, 129.12, 128.89, 127.51, 82.04, 65.05, 55.68, 50.25, 48.82, 46.05, 37.75, 28.46. - 15 A. Contini, Unpublished results. On the Rac1 side, interactions with Tiam1 are mediated by two loops, switch 1 (AAs 25-39) and switch 2 (AAs 57-75), and by non-conserved residues between switches, ensuring proper GEF/Rac1 pairing. (Worthylake, D. K.; Rossman, K. L.; Sondek, J., Nature 2000, 408, 682.) Preliminary results from our laboratory show hot and warm spots in the 13 residue long helix of Tiam1, CR3 (I1187-L1199); however, this portion cannot be used as a standalone peptide inhibitor, since is predicted to be disordered. However, we observed trough preliminary calculations that non-natural helical peptides mimicking the Tiam1 CR3 sequence could maintain the ability to bind Rac1, without altering the conformation of switch 1 and 2.
