This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. This Accepted Manuscript will be replaced by the edited, formatted and paginated article as soon as this is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
In this work, amorphous carbon very thin layers coated on Nb$_2$O$_5$ nanosheets flexible composite have been successfully synthesized. The composite delivers a discharge capacity of 396 mAh g$^{-1}$ after 100 cycles at a current density of 100 mA g$^{-1}$, which is very much higher than for bare Nb$_2$O$_5$ nanosheets.

Lithium-ion batteries (LIBs) have achieved successful applications in portable electronics and become promising power sources in transportation. As one of the most important anodes in commercial LIBs, graphite has limited the development of safe and high-capacity batteries, due to its low charge-discharge plateau and low theoretical capacity (374 mAh g$^{-1}$). In the past several years, nanostructured transition metal oxides (Fe$_2$O$_3$, Fe$_3$O$_4$, MnO, SnO$_2$, NiO, Co$_3$O$_4$, CuO, etc.) have received intensive attention due to their high charge/discharge capacity and higher discharge plateau compared to graphite.[2-10] Most of these materials, however, suffer from volume change during charge/discharge processes, which is detrimental to their cycle life. Thus, it is still a challenge to explore high-capacity, stable anode for advanced LIBs.

In the early 1980s, Reichman and Bard reported the feasible application of Nb$_2$O$_5$ as a cathode in nonaqueous lithium cells.[11] Recently, orthorhombic Nb$_2$O$_5$ (T-Nb$_2$O$_5$) has been reported to be an intercalation pseudocapacitive material, with a crystalline network which offers two-dimensional transport pathways and little structural change on intercalation.[12] This intercalation facilitates charge storage within short periods of time. Inspired by the lithium-intercalation characteristics of T-Nb$_2$O$_5$, many groups have investigated the synthesis and electrochemical behaviour of Nb$_2$O$_5$ materials. A series of Nb$_2$O$_5$ nanostructures have been obtained, including nanofibers,[13] nanotrees,[14] nanotube arrays,[15] nanowires,[16] nanobelts,[17] nanorods,[18] hollow nanospheres,[19] microspheres,[20] nanosheets/nanosheets,[21,22] etc.

The lithium storage properties of Nb$_2$O$_5$-based electrode, have been intrinsically limited by its poor electrical conductivity (σ ≈ 3 × 10$^{-8}$ S cm$^{-1}$) and slow ion diffusion, which results in low rate performance.[23] To address this question, many efforts have been focused on the synthesis of Nb$_2$O$_5$/carbon hybrid materials incorporating various types of carbon (carbon nanotubes, graphene, and other carbon materials) to enhance their electrochemical performance.[24-27]

Recently, our group found that an amorphous carbon coating layer can effectively enhance the capacity, cycle life, and rate performance of electrode materials, in which the amorphous carbon layer not only improved the electronic conductivity of the electrode material, but also contributed to high capacity.[28] First-principles calculations indicated that the presence of defects would facilitate the adsorption and diffusion of lithium on defective graphene, and even provide a high capacity of about 1675 mAh g$^{-1}$.[10-12] In addition, Nishidate and Hasegawa studied the possibilities for the diffusion and accumulation of lithium on defective single-wall carbon nanotubes (SWNTs) using density-functional theory.[33] Kotakoski et al. reported that their amorphous carbon membrane consisted of multivacancy structures constructed of rotated hexagons and other polygons, and could be considered to be defective graphene.[34] Recently, our group synthesized NbO$_x$@C nanoparticles through oleyamine-assisted hydrothermal method followed by calcination.[35] The NbO$_x$@C nanoparticles, which were composed of NbO$_2$, displayed a discharge capacity of about 298 mAh/g after 200 cycles at 100 mA/g. In this work, we have realized high-capacity Nb$_2$O$_5$ nanosheets through coating them with ultrathin amorphous carbon layers, and found that Nb$_2$O$_5$@C nanosheets could deliver a discharge capacity of 396 mAh g$^{-1}$ after 100 cycles at a current density of 100 mA g$^{-1}$, which is very much higher than for bare Nb$_2$O$_5$ nanosheets.
the oleic acid on the surfaces of the Nb$_2$O$_5$ nanosheets. The carbon content in the Nb$_2$O$_5$@C sample was confirmed to about 8.1\% by thermogravimetric analysis (TGA) (Fig. S1 in the Supporting Information (S)). In addition, the crystalline phase of Nb$_2$O$_5$ after carbon coating was almost unchanged, although the intensity of the peaks obviously increases owing to the heat-treatment at high temperature. Both the Nb$_2$O$_5$ nanosheets and the Nb$_2$O$_5$@C nanosheets could be well indexed to the peaks of orthorhombic Nb$_2$O$_5$ according to the standard card (JCPDS No. 27-1003).

The shape and morphology of the Nb$_2$O$_5$ nanosheets and Nb$_2$O$_5$@C nanosheets were further characterized by scanning and transmission electron microscopy (SEM and TEM). Fig. 2A and B presents SEM images of the as-synthesized Nb$_2$O$_5$ nanosheets. As shown in Fig. 2B, the nanosheets are flexible. In this work, we found that our method is highly repeatable, and there is also an important effect on the morphology of the final products from using different ratios of en to distilled water (Figs. S2-S5). Herein, the en might play an important role as a structure-directing reagent. After the coating treatment, the shape of the Nb$_2$O$_5$@C nanosheets remained the same, as shown in Fig. 2C and D. This is because the coating layer is extremely thin, which is an important feature of our method. 28-30

The TEM images give further detailed information on the Nb$_2$O$_5$ nanosheets (Fig. 3A and B) and the Nb$_2$O$_5$@C nanosheets (Fig. 3C and D). As shown in Fig. 3A and C, both the Nb$_2$O$_5$ nanosheets and the Nb$_2$O$_5$@C nanosheets are several nanometers thick. As shown in Fig. 3B, the distance between layers is measured to be 0.42 nm, which is in agreement with the lattice spacing of (001) crystalline planes (001). It was reported that the interspaces between the (001) planes provide natural pathways for lithium-ion transport throughout the ab-plane with low energy barriers. 12 In addition, as pointed out before, the en could structurally direct the growth of Nb$_2$O$_5$ nanosheets along the [001] direction, 12 which might be due to the strong hydrogen bonding between en and the oxygen atoms on the (001) planes, hindering the growth of Nb$_2$O$_5$ along other directions. The TEM image in Fig. 3D clearly indicates the presence of single or double amorphous carbon layers. The formation of single or double carbon layers can be attributed to the carbonization of oleic acid molecules adsorbed on the surfaces of the Nb$_2$O$_5$ nanosheets. Owing to the rich pathways and amorphous carbon layer, the Nb$_2$O$_5$@C nanosheets are expected to have superior electrochemical behavior towards lithium storage.

Standard half-cells were assembled to further investigate
the electrochemical properties of the Nb$_2$O$_3$ and Nb$_2$O$_5$@C anodes. Galvanostatic charge–discharge cycling, cycling stability measurements, and rate capability tests were conducted to investigate the lithium storage properties. Fig. 4 displays charge–discharge curves of the Nb$_2$O$_3$ and Nb$_2$O$_5$@C electrodes for the 1st, 2nd, 50th, and 100th cycles at a current density of 100 mA g$^{-1}$. The typical sloped curves for both the Nb$_2$O$_3$ nanosheets (Fig. 4A) and the Nb$_2$O$_5$@C nanosheets (Fig. 4B) indicate the intercalation-type electrochemical reaction and that the intercalation of Li$^+$ into Nb$_2$O$_3$ and Nb$_2$O$_5$@C electrodes remains a single-phase process. There was no biphasic interface formation during the entire charge-discharge process, which could be verified by the lack of a constant cell voltage plateau.$^{13}$ In the first charge-discharge process, the discharge and the reversible capacity of the Nb$_2$O$_3$ electrode was 662.7 mA g$^{-1}$ and 509.5 mA g$^{-1}$, respectively, while the Nb$_2$O$_5$@C electrode could present a capacity of 1363.8 mA g$^{-1}$ in discharge and a reversible capacity of 563.4 mA g$^{-1}$, as shown in Fig. 4. In summary, the Nb$_2$O$_5$@C exhibits extra capacity compared to the pure Nb$_2$O$_3$ electrode.

![Fig. 5 Cycling performance of Nb$_2$O$_3$ nanosheets and Nb$_2$O$_5$@C nanosheets at 100 mA g$^{-1}$.](image)

A highly reversible and stable cycling performance is one of the most important factors in measuring lithium storage properties. Therefore, cycling measurements were conducted to characterize the lithium storage behavior of Nb$_2$O$_3$ and Nb$_2$O$_5$@C. Fig. 5 shows the cycling performances and coulombic efficiency curves of the synthesized materials at 100 mA g$^{-1}$ in the voltage range of 0–3.0 V. The discharge capacity of the first ten cycles for Nb$_2$O$_5$@C and pure Nb$_2$O$_3$ both significantly decrease, and then stabilize at 396 mA h g$^{-1}$ and 225 mA h g$^{-1}$, respectively. From the coulombic efficiency curves, we calculated that the coulombic efficiency of Nb$_2$O$_5$@C electrode increases from 41.3% at the first cycle to near 100% after a few cycles, while that of Nb$_2$O$_3$ electrode rises from 72.7% at the first cycle to 87.6% after a few cycles.

This work was supported by the National Natural Science Foundation of China (Grant Nos. 51302079) and the Australian Automotive Cooperative Research Centre (CRC-2020). We also thank Dr Tania Silver from Institute for the improvement. This Nb$_2$O$_5$-carbon structure therefore provides a new design for high-performance Nb$_2$O$_3$-based anode materials.

In conclusion, we have successfully synthesized Nb$_2$O$_3$ nanosheets by the solvothermal method using an as the alkaline source. The Nb$_2$O$_5$@C nanosheets were further obtained through our well-established immersion/annealing techniques involving oleic acid. The as-obtained Nb$_2$O$_5$@C nanosheets display a discharge capacity of 396 mA h g$^{-1}$ after 100 cycles at a current density of 100 mA g$^{-1}$ due to their amorphous carbon coating, which could contribute to high lithium storage capacity. The as-obtained Nb$_2$O$_5$@C nanosheets are promising for advanced battery application in the future.

The amorphous carbon layer plays a very important role in improving the electrochemical performance of Nb$_2$O$_3$ from the point of view of improving electronic and ionic conductivity, as well as providing high capacity. Compared with pure Nb$_2$O$_3$, the presence of carbon efficiently enhances the electronic conductivity and protects the Nb$_2$O$_3$ from pulverization, which results in improved rate performance and excellent cyclability.

![Fig. 6 Rate performance of Nb$_2$O$_3$ nanosheets and Nb$_2$O$_5$@C nanosheets at various current densities.](image)

Fig. 6 shows the rate capability of the Nb$_2$O$_3$ nanosheets and Nb$_2$O$_5$@C nanosheets, which indicates a decreasing trend in capacity for both electrodes with increasing current rates. When the current rate gradually increases from low current density (100 mA g$^{-1}$) to high current density (1 A g$^{-1}$), the capacity of the Nb$_2$O$_3$ and Nb$_2$O$_5$@C drops from 209 and 405 mA h g$^{-1}$ to 105 and 250 mA h g$^{-1}$, respectively. When the current density returns to 100 mA g$^{-1}$, the specific storage capacity of Nb$_2$O$_5$@C reaches 370 mA h g$^{-1}$ for Nb$_2$O$_5$@C electrode, however only 186 mA h g$^{-1}$ for Nb$_2$O$_5$, as shown in Fig. 6. It is believed that the carbon coating is responsible for the improvement. This Nb$_2$O$_5$-carbon structure therefore provides a new design for high-performance Nb$_2$O$_3$-based anode materials.

Superconducting and Electronic Materials (University of Wollongong) for revising our manuscript.

Amorphous Carbon Layer Contributing Li Storage Capacity in Nb$_2$O$_5$@C Nanosheets

Lei Wang, Boyang Ruan, Jiantie Xu, Hua Kun Liu and Jianmin Ma

High-capacity of Nb$_2$O$_5$ nanosheets have been successfully realized through introducing amorphous carbon layers, which have been demonstrated to have a large capacity owing to the existence of defects on amorphous carbon layers.
