LaF$_3$-coated Li[Li$_{0.2}$Mn$_{0.56}$Ni$_{0.16}$Co$_{0.08}$]O$_2$ as cathode material with improved electrochemical performance for lithium ion batteries

Qingliang Xie$^a$, Zhibiao Hu$^b$, Chenzhao Zhao$^b$, Shuirong Zhang$^a$ and Kaiyu Liu$^{a,b,*}$

In this article, pristine Li-rich layered oxide Li[Li$_{0.2}$Mn$_{0.56}$Ni$_{0.16}$Co$_{0.08}$]O$_2$ porous microspheres had been successfully synthesized by a urea combustion method, and then coated with 1%wt LaF$_3$ via a facile chemical precipitation route. The structures and morphologies of both pristine and LaF$_3$ coated Li$_{1-x}$Mn$_{0.54}$Ni$_{0.16}$Co$_{0.08}$O$_2$ were performed by X-ray diffraction (XRD), field-emission scanning electron microscopy (FESEM) and high resolution transmission electron microscope (HR-TEM). The results reveal the obtained particles possess the morphologies of porous microspheres, and a LaF$_3$ layer with thickness of 5-8 nm is coated on the surface of Li$_{1-x}$Mn$_{0.56}$Ni$_{0.16}$Co$_{0.08}$O$_2$ particle. As lithium ion battery cathodes, the LaF$_3$ coated sample, compared with the pristine one, has shown a significantly improved electrochemical performances: the initial Columbic efficiency improves from 75.36% to 80.01% and the rate capability increased from 57.4 mAh g$^{-1}$ to an extremely high capacity of 153.5 mAh g$^{-1}$ at 5C. The decreased electrochemical impedance spectroscopy (EIS) reveals that the enhanced electrochemical performance of the surface coating is mainly due to lower charge transfer resistance.

**Introduction**

In order to meet the requirements of application in electric vehicles (EVs) and hybrid electric vehicles (HEVs), searching for safety, low-cost, long lifetime, high energy density and power density cathode materials has been one of the most important subjects in LIBs$^{1-3}$. Li-rich layered oxides xLi$_2$MnO$_3$·(1-x)LiMO$_2$ (M = Ni, Co, Mn or combinations) has been regarded as one of the most promising candidate due to its extraordinarily high theoretical discharge capacity of more than 250 mAh g$^{-1}$ and possess high operating potential over 3.7 V (vs. Li/Li$^+$)$^{14-16}$. However, several drawbacks impede the commercialization of Li-rich cathodes material. The first problem is the enormous irreversible capacity loss of 40-100 mAh g$^{-1}$ in the first cycle depending on the composition when charge up to 4.6 V. The irreversible capacity loss can be attributed to the extraction of Li$_2$O followed by an elimination of the oxide ion vacancies from the structure during the first charge, leading to fewer insertion-extraction sites of lithium ions in the subsequent discharge process$^{7,10}$. In addition, the relatively low electron conductivity of Mn-contained layered component and high cut off operating voltage, resulting in poor rate capability during the electrochemical cycling process$^{11,12}$.

Previous reports demonstrate that surface coating or modifications is a valid method to enhance the electrochemical performance of cathode materials for LIBs when they cycled on many occasions or charged at a high cut-off voltage (e.g., 4.7 V)$^{15-18}$. Among all surface modification materials, the metal fluoride such as AlF$_3$, CaF$_2$, CeF$_3$, LiF has been extensively turned out to be an effective approach to improve electrochemical performance of lithium rich layered oxides. Generally, the metal fluoride is believed to suppress the HF corrosion which is responsible for better cycle stability$^{19-22}$. Furthermore, Zheng et al. reported the AlF$_3$ coated layer can reduce the activity of extract oxygen and suppressed the electrolyte decomposition at voltages above 4.5V, resulting in improved Columbic efficiency and cycling stability$^{23}$. Sun et al. also indicate that AlF$_3$ coating layer can induce the transformation of the layer phase to spinel phase. The formation of spinel phase can play a role as fast lithium ion conductor, and help to improve the rate capability$^{24}$.

LaF$_3$ is another commonly used metal fluoride. Herein, the opposite ion La$^{3+}$ has an ionic radii of ~106.3 pm, which is larger than Mn$^{3+}$, Co$^{3+}$ and Ni$^{2+}$. Thus a slight doping of La$^{3+}$ on the surface of Li-rich layered oxides may lead to the formation of some defects and/or vacancies, and these formed defects and/or vacancies should be helpful for the intercalation/deintercalation of lithium ion$^{25}$. In the present study, a small amount of LaF$_3$ (i.e., 1wt%) is coated on the surface of Li[Li$_{0.2}$Mn$_{0.56}$Ni$_{0.16}$Co$_{0.08}$]O$_2$ microspheres. Experimental results show that the LaF$_3$ coated

Li$_2$Mn$_{0.56}$Ni$_{0.16}$Co$_{0.08}$O$_2$, compared with the pristine Li$_2$Mn$_{0.56}$Ni$_{0.16}$Co$_{0.08}$O$_2$, exhibit a huge improvement on initial Coulombic efficiency and rate capability. The reasons for the improvements of electrochemical performance via LaF$_3$ coating were discussed in detail in context.

Experimental

2.1 Preparation of pristine and LaF$_3$-coated samples

All raw materials were analytical-grade and used as received. The Li[Li$_2$Mn$_{0.56}$Ni$_{0.16}$Co$_{0.08}$]O$_2$ porous sphere were prepared via a facile urea combustion method, described as follows: 0.5112 g LiNO$_3$ (5% Li excess), 0.2792 g Ni(NO$_3$)$_2$·6H$_2$O, 1.301 g aqueous solution of Mn(NO$_3$)$_2$ (50wt%), 0.1397 g Co(NO$_3$)$_2$·6H$_2$O and 1.098 g CO(NH$_2$)$_2$ were dissolved together in 5 ml distilled water to form a uniform solution. Afterwards, the obtained mixed solution was heated in a muffle furnace at 450°C for 40 min under air, and then cooled down naturally to room temperature before adding ammonia solution. The molar ratio of La to F was regulated to 1:3 and the pH value of the obtained solution was adjusted to 7.0 by adding ammonia solution. The molar ratio of La to F was regulated to 1:3 and the coating amount of LaF$_3$ was set to 1 wt% of the parent cathode material. The obtained solution was constantly stirred at 80°C until the solvent was evaporated. Afterwards, the wet powder was dried at 80°C in a vacuum drying oven until the solvent was completely removed. Finally, the dry powders were further annealed in N$_2$ atmosphere at 450°C for 4 h to gain the LaF$_3$-coated Li[Li$_2$Mn$_{0.56}$Ni$_{0.16}$Co$_{0.08}$]O$_2$.

2.2 Structure and morphology characterizations

The crystalline phases of the obtained samples were characterized by X-ray diffractometer (DX-2007 LiaoNing DanDong) at a scanning rate of 0.03°/s within 20 degree of 10-80°. SEM images were performed using a Quanta FEG 250 field emission scanning electron microscope (FEI, Electron optics, B.V.). EDX spectrum was performed using an EDAX system. The surface microstructure and selected area electron diffraction (SAED) of coated sample was observed by transmission electron microscope (TEM, JEM-2100F).

2.3 Electrochemical characterization

Electrode slurry was fabricated by mixing 80wt% of active material, 10wt% of carbon black and 10wt% of polyvinylidene difluoride (PVDF) binder with a certain amount of N-methyl-2 pyrrolidine (NMP) solvent. Then the slurry mixture was pasted on an aluminum foil and dried at 80°C for 8 h in a vacuum drying oven. Finally, the dried aluminum foil were cut into round disk with a diameter of 12 mm and the mean mass loading of active materials were about 2.1 mg cm$^{-2}$. The coin cell (CR2016) was assembled in an argon-filled glove box using pure lithium foils as reference and counter electrode. Commercial LBC 301 LiPF$_6$ solution (ShenZhen XinZhouBang) was used as electrolyte and thin polymer acted as separator. The charge-discharge test of assembled cells was performed using NEWARE battery test systems in a range voltage of 2.0-4.7 V at room temperature (about 30°C). Electrochemical impedance spectroscopy (EIS) measurements were performed using an electrochemical workstation (CHI660D, ShangHai ChenHua) in a frequency range of 0.01MHz to 0.1MHz and open circuit voltage of 3.2 V.

Result and discussion

3.1 Structure and morphologies of pristine and LaF$_3$-coated Li[Li$_2$Mn$_{0.56}$Ni$_{0.16}$Co$_{0.08}$]O$_2$

Fig. 1 shows XRD patterns of pristine and 1wt% LaF$_3$-coated Li[Li$_2$Mn$_{0.56}$Ni$_{0.16}$Co$_{0.08}$]O$_2$. All the sharp diffraction peaks can be indexed to a hexagonal α-NaFeO$_2$ type structure with a space group R-3m. Adjacent peaks of (006)/(012) and (108)/(110) were divided clearly, indicating that each sample has good crystal structure. Weak XRD peaks observed within 20 degree of 20 and 25° (marked by *) suggest the periodic occupation of Li$^+$ ions in the transition metal layers of crystalline LiMn$_2$O$_4$, and the resultant LiMn$_2$O$_4$-type cation arrangements indicate the coexistence of both crystalline Li$_3$Mn$_2$O$_3$ (also referred as layered Li[Li$_{1/3}$Mn$_{2/3}$]O$_2$) and LiNi$_{0.4}$Co$_{0.6}$Mn$_{0.0}$O$_2$.$^{21-22}$ No LaF$_3$ and other impurities diffraction peaks can be observed in the XRD pattern, indicating that a little amount of LaF$_3$ is only coated on the surface of the Li[Li$_2$Mn$_{0.56}$Ni$_{0.16}$Co$_{0.08}$]O$_2$, and the bulk structure of the Li[Li$_2$Mn$_{0.56}$Ni$_{0.16}$Co$_{0.08}$]O$_2$ remains unchanged after surface modification process.
cathode. Firstly, the sphere-like structure can have a good stability during cycling. Secondly, the primary nanoparticles within microspheres can provide a short pathway for the intercalation/deintercalation of lithium ion.\textsuperscript{27-29} Thus, the electrochemical performances should be worth to be expected after surface modification with function materials such as LaF\(_3\).

SEM image of LaF\(_3\)-coated porous microspheres was shown in Fig. 2c, compared with the pristine sample (Fig. 2b), a bright coating layer could be observed on the surface of coated, and the gap between nanoparticles is less distinguished due to the existence of the coating layer. To further study the structure of surface coating layer, a high resolution transmission electron microscope (HR-TEM) is carried out, and the result is showed in Fig. 2d. The lithium rich layered oxides are the nanosized mixture of Li\(_{0.56}\)Mn\(_{0.40}\)Ni\(_{0.08}\)O\(_2\). In Fig. 2d, the Li\(_{0.56}\)Mn\(_{0.40}\)O\(_2\) domain has been successfully captured by HR-TEM, and the lattice fringes with a spacing of 0.43 nm can be assigned to the (020) crystal face of Li\(_{0.56}\)Mn\(_{0.40}\)O\(_2\) component. Also, from SAED pattern in Fig.S1, the diffraction dots of (003), (101), (104) and (107) crystal plane can be clearly presented, which are consistent with the XRD diffraction dots of (003), (101), (104) and (107) crystal plane. From Fig.2d, the Li\(_{0.56}\)Mn\(_{0.40}\)O\(_2\) also can be denoted as 0.5Li\(_{0.56}\)Mn\(_{0.40}\)O\(_2\)-0.5Li\(_{0.56}\)Ni\(_{0.08}\)Mn\(_{0.40}\)O\(_2\). Also shown in Fig. 2c, compared with the pristine sample (Fig. 2b), a bright coating layer could be observed on the surface of Li\(_{0.56}\)Mn\(_{0.40}\)Ni\(_{0.08}\)O\(_2\) coated, and the gap between nanoparticles is less within microspheres can provide a short pathway for the extraction of Li\(_2\)O followed by an elimination of the oxide ion (i.e., 0.560 : 0.160 :0.08). The calculated atomic ratio of La : Mn is 1.0 : 50.2 from the EDS analysis, and the theoretical data based on 1wt% LaF\(_3\) coating should be 1.0 : 50.6. These results indicate that the actual element composition of as-prepared pristine and 1wt% LaF\(_3\)-coated sample are consistent with the experimental design. It should be emphasized that, the content of O and F is difficult to be accurately detected by EDS. However, the EDS image also shows the coexistence of O and F element.

![Fig. 2](image-url)  
\textbf{Fig. 2} SEM images of the pristine Li[Li\(_{0.2}\)Mn\(_{0.56}\)Ni\(_{0.16}\)Co\(_{0.08}\)]O\(_2\) at a (a) low magnification and (b) high magnification, (c) 1 wt% LaF\(_3\)-coated Li[Li\(_{0.2}\)Mn\(_{0.56}\)Ni\(_{0.16}\)Co\(_{0.08}\)]O\(_2\), (d) HR-TEM and SAED (selected area electron diffraction) image of LaF\(_3\)-coated Li[Li\(_{0.2}\)Mn\(_{0.56}\)Ni\(_{0.16}\)Co\(_{0.08}\)]O\(_2\).

In order to further distinguish the difference of the surface structure after coating, the XPS spectrums of pristine and coated samples are carried out as shown in Fig.S2. The characteristic binding energies of La3d and F1s are 834.89 eV and 684.64 eV, respectively, which are in accordance with those of pure LaF\(_3\).\textsuperscript{13} Compared with bare Li[Li\(_{0.2}\)Mn\(_{0.56}\)Ni\(_{0.16}\)Co\(_{0.08}\)]O\(_2\), the Ni2p, Co2p and Mn2p peaks (in Fig. S2) of LaF\(_3\)-coated Li[Li\(_{0.2}\)Mn\(_{0.56}\)Ni\(_{0.16}\)Co\(_{0.08}\)]O\(_2\) have no obvious chemical shift, indicating that the Ni, Co and Mn environments in the structure have not been changed. However, the intensity of each peak decreases obviously after coating, which is attributed to the formation of the LaF\(_3\) layer on the surface of Li[Li\(_{0.2}\)Mn\(_{0.56}\)Ni\(_{0.16}\)Co\(_{0.08}\)]O\(_2\).

Furthermore, the selected area EDS image and corresponding element analysis of 1wt% LaF\(_3\)-coated Li[Li\(_{0.2}\)Mn\(_{0.56}\)Ni\(_{0.16}\)Co\(_{0.08}\)]O\(_2\) is shown in Fig.3. The calculated element ratio of Ni : Co : Mn in Fig. 4 should be 0.560 : 0.159 : 0.082, which is close to the chemical formula of Li[Li\(_{0.2}\)Mn\(_{0.56}\)Ni\(_{0.16}\)Co\(_{0.08}\)]O\(_2\) (i.e., 0.560 : 0.160 :0.08). The calculated atomic ratio of La : Mn is 1.0 : 50.2 from the EDS analysis, and the theoretical data based on 1wt% LaF\(_3\) coating should be 1.0 : 50.6. These results indicate that the actual element composition of as-prepared pristine and 1wt% LaF\(_3\)-coated sample are consistent with the experimental design. It should be emphasized that, the content of O and F is difficult to be accurately detected by EDS. However, the EDS image also shows the coexistence of O and F element.

![Element dispersive spectrum (EDS) of 1wt% LaF\(_3\)-coated Li[Li\(_{0.2}\)Mn\(_{0.56}\)Ni\(_{0.16}\)Co\(_{0.08}\)]O\(_2\)](image-url)  
\textbf{Fig. 3} Element dispersive spectrum (EDS) of 1wt% LaF\(_3\)-coated Li[Li\(_{0.2}\)Mn\(_{0.56}\)Ni\(_{0.16}\)Co\(_{0.08}\)]O\(_2\), the inserted are the selected area and detailed element analysis.

Fig. 4 comparatively reveals the initial charge-discharge and corresponding dQ/dV curves of pristine and 1wt% LaF\(_3\)-coated Li[Li\(_{0.2}\)Mn\(_{0.56}\)Ni\(_{0.16}\)Co\(_{0.08}\)]O\(_2\) electrodes within 2.0-4.7 V at 0.1C (1C = 200 mA g\(^{-1}\)). The initial charge/discharge capacity of the pristine and 1wt% LaF\(_3\)-coated sample are 330/249 and 339/272 mAh g\(^{-1}\) (Fig. 4a), give a Coulombic efficiency of 75.4 and 80.4%, respectively. It is clear that the irreversible capacity loss has been decreased from 81 to 67 mAh g\(^{-1}\). As we know, one of primary disadvantages of LLOs (lithium rich layered oxides) cathodes is the enormous irreversible capacity loss of 40-100 mAh g\(^{-1}\) in the first cycle, and the irreversible capacity loss can be attributed to the extraction of Li\(_2\)O followed by an elimination of the oxide ion vacancies from the structure. The surface modification with metal fluoride can reduce the activity of extract oxygen. Thus, the initial Coulombic efficiency of LLOs can be effectively improved. In other words, the improved Coulombic efficiency should be attributed to the fact of that “LaF\(_3\) coated sample, compared with the pristine one, presents higher discharge.
capacity under close charge capacity.

As reported by many literatures\textsuperscript{23, 24, 34}, the surface modification can effectively improve the initial Coulombic efficiency. Zheng et al.\textsuperscript{23} reported coating layer can act as a “buffer” layer to enhance the formation of inactive oxygen and restrain the secondary reaction of electrolyte oxidation caused by active oxygen species. Thus, an improved Coulombic efficiency can be expected.

Fig. 4b is the dQ/dV curves of pristine and coated sample. During the first charge process, an anodic peak nearby 4.00 V can be ascribed to the de-intercalation of Li\textsuperscript{+} ions from LiNi\textsubscript{0.8}Co\textsubscript{0.2}Mn\textsubscript{0.7}O\textsubscript{2} phase and the oxidation of Ni\textsuperscript{2+} ions, and the sharp anodic peak within 4.50-4.52 V corresponds to the transformation of Li\textsubscript{2}MnO\textsubscript{3} to layered MnO\textsubscript{2} and the oxidation of Co\textsuperscript{3+} ions. In the initial discharge process, two cathodic peaks around 3.75 and 3.30 V indicate the intercalation of Li\textsuperscript{+} ions into layered LiNi\textsubscript{0.8}Co\textsubscript{0.2}Mn\textsubscript{0.7}O\textsubscript{2} and previously formed MnO\textsubscript{2}, respectively. Compared with pristine Li[Li\textsubscript{1/3}Ni\textsubscript{0.56}Co\textsubscript{0.16}O\textsubscript{2}]/Li, the coated sample has a high discharge voltage (Fig. 4b, red curve), which demonstrates that the coating layer can reduce the polarization to a certain degree.

The discharge capacity and cycling performance of the electrode materials at an elevated current density are significant parameter for cathode. The discharge capacity and cycling stability of pristine and 1wt% LaF\textsubscript{3}-coated Li[Li\textsubscript{1/3}Ni\textsubscript{0.56}Co\textsubscript{0.16}O\textsubscript{2}]/Li electrodes at a current density of 0.1C between 2.0 and 4.7V.

![Fig. 4 The initial charge/discharge voltage profiles and corresponding differential capacity (dQ/dV) curves of pristine Li[Li\textsubscript{1/3}Ni\textsubscript{0.56}Co\textsubscript{0.16}O\textsubscript{2}]/Li and 1wt% LaF\textsubscript{3}-coated Li[Li\textsubscript{1/3}Ni\textsubscript{0.56}Co\textsubscript{0.16}O\textsubscript{2}]/Li electrodes at a current density of 0.1C between 2.0 and 4.7V.](image)

Although the Li-rich layered xLi\textsubscript{2}MnO\textsubscript{3}/(1-x)LiMO\textsubscript{2} has an extraordinarily high theoretical discharge capacity of more than 250 mAh g\textsuperscript{-1} and possess high operating potential of 4.6–4.8 V (vs. Li\textsuperscript{+}/Li), the poor rate capacity was one of the most important drawback that impede the commercialization of this cathode materials\textsuperscript{35–37}. In this paper, the rate capability of the pristine and LaF\textsubscript{3}-coated Li[Li\textsubscript{1/3}Ni\textsubscript{0.56}Co\textsubscript{0.16}O\textsubscript{2}]/Li electrodes were performed in Fig. 6a. Apparently, the discharge capacity decrease of each sample with elevated current density. The LaF\textsubscript{3}-coated electrode exhibits a stable discharge capacity of 273.2, 229.3, 202.7 or 178.2 mAh g\textsuperscript{-1} at current density 0.1C, 0.5C, 1C or 2C, respectively. Even when the current density is increased to a high value of 5C, the electrode still delivers a high discharge capacity of 153.5 mAh g\textsuperscript{-1}. While, the pristine sample only shows a discharge capacity 121 or 58.2mAh g\textsuperscript{-1} at current density of 2C or 5C. As shown in Fig. 6b and c, the discharge profiles at various C rates of pristine and 1wt% LaF\textsubscript{3}-coated Li[Li\textsubscript{1/3}Ni\textsubscript{0.56}Co\textsubscript{0.16}O\textsubscript{2}]/Li. The capacity and
voltage decay with elevated current density has been denoted by arrow, and it can be seen that the pristine sample has a more serious decay. According to above results, the rate capability of Li[Li$_{0.2}$Mn$_{0.56}$Ni$_{0.16}$Co$_{0.08}$]O$_2$ has been greatly improved by surface coating with 1wt%. Maybe, the LaF$_3$ can act as a fast Li ion conductor and/or induce the formation of spinel Li-Ni-Mn-O oxide$^{38-40}$, and which facilitate the insertion/extraction of Li ion within the interface of electrode material and electrolyte.

With the purpose of further investigate the mechanism of enhanced electrochemical performance of LaF$_3$-coated Li[Li$_{0.2}$Mn$_{0.56}$Ni$_{0.16}$Co$_{0.08}$]O$_2$, Fig. 7 shows the electrochemical impedance spectroscopy (EIS) of the pristine and LaF$_3$-coated Li[Li$_{0.2}$Mn$_{0.56}$Ni$_{0.16}$Co$_{0.08}$]O$_2$ after 3 cycles before charge. It should be mentioned out that the spectroscopy is fitted using impedance matching software ZSimDemo 3.30 original spectrum in Fig.S3. The high-frequency semicircle and low-frequency slope line was given by the Nyquist plots, in which the high-frequency semicircle is related to the charge transfer resistance (Rct) in the electrode/electrolyte and the low-frequency slope line on behalf of the impedance of the lithium ion diffusion in bulk electrode materials. Obviously, compared to the pristine samples, the LaF$_3$-coated samples have a much smaller Rct value. The Rct value of the pristine samples was 116.2 $\Omega$, while the LaF$_3$-coated samples exhibit an Rct value of 89.66 $\Omega$. As mentioned above, it demonstrates that the LaF$_3$ acted as a very stable conductor layer to improve the electrochemical conductivity of as-prepared Li[Li$_{0.2}$Mn$_{0.56}$Ni$_{0.16}$Co$_{0.08}$]O$_2$. That is the reason why the LaF$_3$ coating layer results in the excellent rate compatibilitys and higher coulombic efficiency of the electrode.

Conclusions

As we all know, the initial coulombic efficiency and the poor rate performance are the main drawbacks that impeding the possible commercialization of lithium rich layered oxides such as Li[Li$_{0.2}$Mn$_{0.56}$Ni$_{0.16}$Co$_{0.08}$]O$_2$. In this paper, the pristine Li[Li$_{0.2}$Mn$_{0.56}$Ni$_{0.16}$Co$_{0.08}$]O$_2$ porous microspheres has been successfully synthesized by a urea combustion method and then uniformly coated with LaF$_3$ using a simple chemical precipitation method. The coating layer has a reasonable thickness of 5-7 nm. As lithium ion battery cathode, the LaF$_3$-coated Li[Li$_{0.2}$Mn$_{0.56}$Ni$_{0.16}$Co$_{0.08}$]O$_2$ exhibits greatly enhanced electrochemical performance compared with pristine sample. The initial coulombic efficiency has been improved from 75.36% to 80.01%. Especially, the discharge capacity increases from 57.4 to 153.5 mAh g$^{-1}$ at 5C. Maybe, the coating layer of LaF$_3$ can act as “buffer” and “conductor” to enhance initial Coulombic efficiency and rate capability.
