# Theoretical Studies on Gas-Phase Kinetics and Mechanism of Habstraction Reaction from Methanol by ClO and BrO Radicals

Samiyara Begum and Ranga Subramanian<sup>1</sup>

Received (in XXX, XXX) Xth XXXXXXXXX 20XX, Accepted Xth XXXXXXXX 20XX 5 DOI: 10.1039/b000000x

The gas-phase kinetics and mechanism of two channel hydrogen (H) abstraction reaction either hydroxyl H-atom or methyl H-atom from methanol (CH<sub>3</sub>OH) by halogen monoxide (XO, X=Cl, Br) radical have been investigated using theoretical approach. The geometry optimization and frequency calculations were performed at M06-2X method and cc-pVTZ basis set. Single point energy calculation of all the species were computed at high level CCSD(T)/cc-pVTZ theory on the M06-2X/cc-pVTZ optimized structure. Weak 10 intermolecular pre-reactive and post-reactive complexes were located at the entrance and exit channel respectively on the potential energy surfaces of all the H-abstraction reactions. The rate constants (k) and branching ratio (φ) of all possible channels were calculated as a function of temperature for a wide range of temperature 200-2500 K. The rate constants were estimated using canonical variational transition state theory (CVT) combined with an Eckart tunneling correction and hindered rotor approximation for low frequency torsional modes. The rate constant calculation shows that the reaction for the H-abstraction from methyl group of CH<sub>3</sub>OH by XO radical leading 15 to hydroxymethyl (CH<sub>2</sub>OH) radical is predominant over the hydroxyl group H-abstraction reaction forming methoxy (CH<sub>3</sub>O) radical for the temperature range of 200-2500 K. Arrhenius equation using three parameters was obtained by fitting the kinetic data for the two channels of H-abstraction by CIO and BrO radicals. The overall rate expression with CIO radical is found to be  $k_{out}(T) = 3.92 \text{ x} \cdot 10^{-1}$  $^{19}T^{1.63}$ exp(-2062/T) and with BrO radical it is  $k_{out}(T) = 1.53 \text{ x} 10^{-20} T^{2.41}$ exp(-2206/T) for the temperature range 200-2500 K.

#### 1. Introduction

Methanol (CH<sub>3</sub>OH) is an oxygenated volatile liquid mostly used as common organic solvent in chemical laboratories and as fuel directly or as a fuel additive with gasoline. It is considered as an 5 alternate fuel as it produces lesser air pollutants in combustion than gasoline.<sup>1,2</sup> Methanol is the most abundant non-methane oxygenated volatile gas in the atmosphere with the estimated global emissions<sup>3</sup> up to 240 Tg year<sup>-1</sup>. In atmosphere, the methanol emission sources includes the plant growth, biomass 10 burning, biofuels, industry, vehicles, plant decay and atmospheric reactions.3-5 The major sink of methanol released into the atmosphere is oxidation by the hydroxyl (OH) radical with atmospheric lifetime of about 10 days.<sup>3</sup> This comparatively longer lifetime may cause it to interact with other atmospheric 15 species. Due to its large emission, it is important to know the fate of methanol in atmosphere.

The chlorinated or brominated species are important from both atmospheric and combustion chemistry point of view. In atmosphere halogen oxide radicals, XO (X=Cl or Br) are 20 formed from the reaction of halogen atom with ozone, heterogeneous oxidation of halogen atom or atmospheric degradation of X containing species (for example, formation of ClO from CFCs, CH<sub>3</sub>Cl).<sup>6-8</sup> Chlorine monoxide (ClO) is also detected at the same level of OH radical concentration near the 25 surface of the burner in ammonium perchlorate combustion process in a hydrogen atmosphere at 1400 K.9,10 The O2-H2 flame doped with X<sub>2</sub> shows the presence of XO radicals. 11,12 There is no information regarding kinetics and mechanism of CH<sub>3</sub>OH+XO reaction. The increasing use of CH<sub>3</sub>OH as direct 30 fuel or as a fuel additive enhances the presence of it in the atmosphere, thereby augments the significance of this study.

The presence of two nonequivalent hydrogen (H) atoms in CH<sub>3</sub>OH leads to the formation of two structural isomers, methoxy (CH<sub>3</sub>O) or hydroxymethyl (CH<sub>2</sub>OH), which are the 35 product radicals. These product radicals are produced by competitive hydroxyl H-abstraction or methyl H-abstraction reaction by XO radicals. In this study, the two possible Habstraction reaction channels from CH<sub>3</sub>OH by XO radical to produce either CH<sub>3</sub>O or CH<sub>2</sub>OH radicals have been studied. The 40 possible pathways are as follows:

$CH_3OH+ClO \rightarrow CH_3O+HOCl$	R1
$CH_3OH+ClO \rightarrow CH_2OH+HOCl$	R2
$CH_3OH+BrO \rightarrow CH_3O+HOBr$	R3
s and $CH_3OH+BrO \rightarrow CH_2OH+HOBr$	R4

The present study focuses on comprehensive insight of two possible H-abstraction reactions, R1 to R4 of CH<sub>3</sub>OH with ClO and BrO radical using theoretical approach. The different 50 thermodynamic and kinetic parameters of the individual

pathways are also discussed over a wide temperature range and is required for atmospheric and combustion reaction modeling. The relative formations of the methoxy and hydroxymethyl radicals are emphasized by the branching ratios. The temperature 55 dependence of branching ratios is important to understand the contribution of the two competitive pathways towards the overall rate constants. Theoretical studies of kinetics and mechanism of the reaction of CH<sub>3</sub>OH with ClO and BrO radicals is a necessary step which will aid experimentalist over a wide range of 60 temperature.

## 2. Computational Methods

Geometry optimization of the reactants (CH<sub>3</sub>OH, XO (X=Cl, Br)), pre- and post-reactive molecular complexes (PreM and 65 PostM respectively), transition states (TS), and product molecules (CH<sub>3</sub>O, CH<sub>2</sub>OH, HOX) involved in the H-abstraction reaction from CH<sub>3</sub>OH by XO radical were carried out employing the Minnesota hybrid meta density functional theory (DFT) level of M06-2X<sup>13,14</sup>, and Dunning's correlation-consistent polarized 70 valence triple-zeta, cc-pVTZ basis set. M06-2X functional is found to be good performer for main group chemistry, in predicting transition state geometry calculation and also performs calculating non-covalent interactions<sup>15</sup> thermochemistry and kinetic parameters. 13,14,16 Frequency 75 calculations of all the species were executed at the same level of theory to judge the stationary points on the potential energy surface as minima (NIMAG=0) or transition states (NIMAG=1). In case of the transition states, the corresponding bond breaking and forming is reflected by the presence of one imaginary 80 frequency associated with it. Intrinsic reaction coordinate (IRC)<sup>17,18</sup> analyses were performed at the same level of theory to obtain the minimum energy path (MEP) of the reactions and to ascertain whether the transition states connect different local minima along the reaction path. Based on the M06-2X/cc-pVTZ 85 optimized structures, the potential energy surface of the titled reaction was refined with single point energy calculation at high level coupled cluster method with single and double excitations and perturbative triples, CCSD(T)/cc-pVTZ. The zero-point energies (ZPE) obtained at M06-2X/cc-pVTZ was added to 90 CCSD(T)/cc-pVTZ energies to obtain the different ZPE corrected energies. All reported calculations were performed employing Gaussian 09 package of programs<sup>19</sup> and GaussView 5.0.9 software<sup>20</sup> was used for the visualization of molecular structures, orbitals and vibrational motions. The spin expectation value,  $_{95}$  < $S^2$ >, at M06-2X level for all doublet systems remained in the range of 0.75-1.00. So, spin contamination was negligible during the progress of the reaction via four different reaction paths R1, R2, R3 and R4. PreMs were found at the entrance channel of the reaction and PostMs were at the exit channel of the reaction. The 100 PreM and PostM complexes have all real frequencies.

The reaction rates were evaluated using canonical variational transition state theory (CVT)<sup>21</sup> with the inclusion of unsymmetrical one dimensional tunneling correction by Eckart<sup>22</sup> over the temperature range 200-2500 K. The rate constants were 5 computed using KISTHELP<sup>23</sup> program. The CVT rate constant,  $k^{CVT}(T)$  is estimated by minimizing generalized transition state<sup>24</sup> rate constant,  $k^{GT}(T,s)$  with respect to reaction coordinate s. s represents the distance along the MEP from the saddle point. Thus,  $k^{CVT}(T)$  with the Eckart tunneling correction  $\chi(T)$  is given

$$k^{CVT}(T) = \chi(T) \min_{s} k^{GT}(T, s)$$

$$= \chi(T) \min_{s} \left(\sigma \frac{k_b T}{h} \frac{Q^{TS}(T, s)}{N_A Q^R(T)} e^{(-V^{\#}(s)/k_b T)}\right)$$

Here,  $k_{h}$  is the Boltzmann's constant, T is the temperature, h is 15 the Planck's constant,  $N_A$  is Avogadro's number,  $V^{\#}$  is potential energy barrier including ZPE correction.  $\sigma$  is the symmetry factor which denotes the reaction path degeneracy.  $\sigma$  is 1 and 3 respectively for H-abstraction from hydroxyl group (path 1) and methyl group (path 2) of CH<sub>3</sub>OH.  $Q^{TS}$  and  $Q^{R}$  are total partition 20 function of the TS and reactants per unit volume. The total partition function terms are consisted of translational, electronic, rotational and vibrational partition functions. Rigid-rotor harmonic oscillator approximation has been used. The low frequency torsional modes of the reactants and the transition 25 states have been treated using hindered rotor approximation while calculating their contribution to the partition functions. Relaxed potential energy scan at M06-2X/cc-pVTZ using the optimized structures at same level have been performed for the low frequency torsional modes to calculate corresponding rotational 30 barrier height of internal rotation. As in our previous study<sup>25</sup>, the rate constant expression does not contain the energy of the molecular complexes and the same argument is applied here.

Spin-orbit effect is important in case of halogen atoms. 26,27 The spin-orbit correction of -0.92 kcal/mol for ClO<sup>28</sup> 35 and -2.79 kcal/mol for BrO<sup>29</sup> were taken into account. The potential energies of ClO radical and pre-reactive molecular complexes (PreM11, PreM12) involving ClO are associated with the spin-orbit correction of -0.92 kcal/mol while BrO and BrO related pre-reactive molecular complexes (PreM21, PreM22) are 40 having -2.79 kcal/mol spin-orbit correction value.

The bonding features of different stationary points on potential energy surface of CH<sub>3</sub>OH+XO (X=Cl, Br) reaction were studied in terms of electronic density at M06-2X/cc-pVTZ using atoms in molecules (AIM) approach by Bader<sup>30,31</sup> as implemented 45 in AIMALL suite of program<sup>32</sup>. The wave function required for AIM calculation was generated from Gaussian 09.

## 3. Results and Discusions

## 3.1. Geometries and vibrational frequencies of the stationary 50 points. The detailed cartesian coordinates of the optimized reactants, pre-reactive (PreM) and post-reactive (PostM) molecular complexes, transition states (TS) and product radicals at M06-2X/cc-pVTZ level of theory are given in ESI Table 1<sup>†</sup> and additional structural parameters in ESI Figure 1<sup>†</sup>. The 55 schematic representation of the two H-abstraction reaction pathways from CH<sub>3</sub>OH by XO radical is shown in Figure 1 and related structural parameters at M06-2X/cc-pVTZ are reported in

Table 1. The potential energy surface of the reactions R1 to R4 with zero point energy correction at CCSD(T)/cc-pVTZ//MO6-60 2X/cc-pVTZ is shown in Figure 2 and Figure 3. Table 2 shows calculated rotational constants and the vibrational frequencies of different stationary points at M06-2X/cc-pVTZ. The electron density, p at bond critical points (BCP) of the chemical bonds (intra or inter) present in all corresponding stationary points of 65 CH<sub>3</sub>OH+XO (X=Cl, Br) reaction is summarized in Table 3. CH<sub>3</sub>OH+ClO reaction (R1, R2): The equilibrium geometry of  $CH_3OH$  is  $C_s$  symmetry and it has two types of non-equivalent H-Two transition states CH<sub>3</sub>O···H···OCl (TS11) and ClO···H···CH<sub>2</sub>OH (TS12) corresponds to the reaction path R1 and 70 R2 (Figure 2) respectively were found along the H-abstraction reaction of CH<sub>3</sub>OH with ClO radical. These two reactions occur by the participation of oxygen atom in ClO radical with the two non-equivalent hydrogen atoms of CH<sub>3</sub>OH. The methyl group orientation results in only one type of transition state TS12 for 75 either syn or anti H-abstraction of the methyl group with respect to hydroxyl group orientation. From Table 2, it is observed that the two transition states, TS11 and TS12, are characterized by imaginary frequencies of 1946i cm<sup>-1</sup> and 1250i cm<sup>-1</sup> respectively. These imaginary frequencies correspond to the vibration of the 80 molecule along its reaction pathway. The movement of hydrogen atom between O<sub>1</sub> and O<sub>2</sub> in TS11 and between C and O<sub>2</sub> in TS12 leads to the product formation. Table 3 shows the electron density, p of different chemical bonds in TS11 and TS12. The ρ value for O<sub>1</sub>-H<sub>0</sub> bond breaking and H<sub>0</sub>-O<sub>2</sub> bond 85 formation in TS11 are 0.176 au and 0.202 au respectively, whereas in TS12, breaking C-H<sub>1</sub> and formation of H<sub>1</sub>-O<sub>2</sub> bonds has electron density values of 0.196 au and 0.131 au respectively. The bonding analysis also shows the presence of other intermolecular bonds namely, H-bonding of Cl-H<sub>1</sub> in TS11 and 90 halogen bonding<sup>33,34</sup> of Cl-O<sub>1</sub> in TS12. The L-parameter<sup>35</sup> which is the ratio of the increase in the bond length being broken over the increase in the bond length being formed is helpful in finding whether the transition state has reactant-like or product-like characteristics. The value of L more than 1 represents a product 95 like TS and less than 1 represents reactant like TS. From Table 2, it is observed that for the reaction CH<sub>3</sub>OH + ClO, the estimated L value is more than 1 along the reaction path R1 and is less than 1 along the path R2. Thus, TS11 is product-like transition state and TS12 is reactant-like transition state. In TS11, O<sub>1</sub>-H<sub>0</sub> bond 100 increases by 24 % (= 0.226 Å) compared to  $O_1$ - $H_0$  bond in the isolated CH<sub>3</sub>OH and H<sub>0</sub>-O<sub>2</sub> bond increases by 19 % (= 0.183 Å) when compared to H<sub>0</sub>-O<sub>2</sub> bond in HOCl product molecule. On the other hand, in TS12, the elongation of C-H<sub>1</sub> bond is about 13 % (= 0.138 Å) compared to C-H<sub>1</sub> bond in the isolated CH<sub>3</sub>OH and  $H_1$ - $O_2$  bond is stretched 38 % (= 0.364 Å) when compared to H<sub>1</sub>-O<sub>2</sub> bond in HOCl molecule. There is a slight shortening of C-O<sub>1</sub> bond distance in both TS11 and TS12 than isolated CH<sub>3</sub>OH molecule. Table 1 shows that the bond angle  $\theta(O_1-H_0-O_2)$  is 165.6° in TS11 and thus attack of ClO on hydroxyl H-atom of 110 CH<sub>3</sub>OH is distorted by 14.4<sup>o</sup> from collinearity. The bond angle

R1 leads to the formation of methoxy radical by the Habstraction from the hydroxyl group of CH<sub>3</sub>OH whereas R2 path 115 gives hydroxymethyl radical results from the methyl group H-

ClO on methyl H-atom is not collinear.

 $\theta(O_2-H_1-C)$  is 166.4° in TS12 which signifies that the attack of

abstraction of CH<sub>3</sub>OH. These two reaction pathways are associated with the formation of H-bonded pre- and post-reactive molecular complex on the potential energy surface connected by the transition states. These molecular complexes are 5 characterized by all real frequencies (NIMAG=0). displays the different intra and intermolecular bond density present in these molecular complexes which are favored by the formation of intermolecular H-bonding or halogen bonding. The pre-reactive complex CH<sub>3</sub>OH···OCl (PreM11) and post-reactive 10 complex CH<sub>3</sub>O···HOCl (PostM11) are connected by TS11. PreM11 is formed by the weak interaction of O-atom of ClO radical and hydroxyl H-atom of CH<sub>3</sub>OH. The complex PostM11 is formed between the O-atom of CH<sub>3</sub>O radical and H-atom of In PreM11, the electron density, ρ of HOCl molecule. 15 intermolecular H<sub>0</sub>-O<sub>2</sub> bond is 0.016 au and in PostM11, O<sub>1</sub>-H<sub>0</sub> has bond density of 0.033 au. The weak intermolecular H<sub>0</sub>-O<sub>2</sub> bond distance is 2.157 Å in PreM11 and  $O_1$ -H $_0$  distance is 1.845 Å in PostM11. In PostM11, there is another intermolecular H-bond, Cl-H<sub>1</sub> of density 0.006 au and of distance 2.951 Å. This Cl-H<sub>1</sub> 20 bond is also present in TS11 with density 0.011 au and distance 2.645 Å. The bond angle  $\theta(O_1-H_0-O_2)$  is  $140^0$  and  $157.2^0$  in PreM11 and PostM11 respectively, which reflects that the atoms involved in bond breaking and forming are not linear in the weak complexes following R1 path. The dihedral angle  $\phi(C_1-O_2-H_0-C_1)$  $_{25}$  O<sub>1</sub>) is found to be -32.0° in PreM11 and it is -51.5° in PostM11. ClO approaches the methyl H-atom of CH<sub>3</sub>OH and forms the weak complex CIO···HCH2OH (PreM12) while complex CIOH···CH2OH (PostM12) is formed after the H-abstraction process following R2 reaction path as shown in Figure 2. 30 PreM12 results from the weak intermolecular interaction of oxygen atom of ClO with the methyl H-atom of CH<sub>3</sub>OH and PostM12 is formed from the weak interaction of H-atom of already formed HOCl with C-atom of CH<sub>2</sub>OH radical for R2 pathway. The newly formed weak intermolecular H<sub>1</sub>-O<sub>2</sub> bond 35 distance is 2.593 Å in PreM12 and C-H<sub>1</sub> bond distance is 2.131 Å in PostM12. In PreM12, H<sub>1</sub>-O<sub>2</sub> bond has density of 0.008 au and in PostM12, electron density for C-H<sub>1</sub> bond is 0.022 au. PostM12 contains another intermolecular H-bond Cl-H<sub>0</sub> with density of 0.012 au and distance of 2.607 Å. The halogen bond Cl-O<sub>1</sub> has 40 density 0.010 au in both PreM12 and TS12. The Cl-O1 bond distance is 3.112 Å in PreM12 and is 3.149 Å in TS12. At M06-2X/cc-pVTZ, the estimated dihedral angle  $\phi(Cl-O_2-H_1-C)$  is  $50.2^0$ and 12.60 in PreM12 and PostM12 respectively. For R2 reaction pathway, the bond angle  $\theta(O_2-H_1-C)$  is determined to be 107.9° in 45 PreM12 and 152.0<sup>0</sup> in PostM12.

CH<sub>3</sub>OH+BrO reaction (R3, R4): The optimized geometric parameters of all the species in the potential energy surface of the CH<sub>3</sub>OH+BrO reaction are given in Table 1. The attack of BrO radical on the hydroxyl H-abstraction (R3) corresponds to 50 transition state, CH<sub>3</sub>O···H···OBr (TS21) and attack on the methyl H-abstraction (R4) corresponds to the transition state,  $BrO\cdots H\cdots CH_2OH$  (TS22). The respective potential energy surface for R3 and R4 pathways are shown in Figure 3 respectively and corresponding bond breaking and bond forming 55 densities are reported in Table 3. From the listed value in Table 3, it is observed that in TS21, electron density, p at BCP of O<sub>1</sub>-H<sub>0</sub> bond breaking is lesser (=0.176 au) than the corresponding ρ (=0.372 au) in isolated CH<sub>3</sub>OH molecule and for the formation

 $H_0$ - $O_2$  bonds  $\rho$  is lesser (=0.196 au) than corresponding bond in 60 the product HOBr molecule (=0.366 au). In TS22, C-H<sub>1</sub> density of bond breaking is 0.201 au and density of H<sub>1</sub>-O<sub>2</sub> bond formation is 0.126 au. The second intermolecular H-bond Br-H<sub>1</sub> in TS21 has density of 0.015 au and distance of 2.630 Å. As reported in Table 2, imaginary frequency associated with the <sub>65</sub>  $O_1$ ··· $H_0$ ··· $O_2$  vibration in TS21 is 1918i cm<sup>-1</sup> and with C··· $H_1$ ··· $O_2$ vibration, it is 1124i cm<sup>-1</sup> in TS22. In case of both ClO and BrO radicals, the magnitude of the imaginary frequency for the transition state involving methyl H-abstraction is less than the hydroxyl H-abstraction path. The L value for TS21 is more than 70 1 and for TS22, it is less than 1. These L values indicate that TS21 is product like whereas TS22 geometry is reactant like. The characteristics of TS21 and TS22 are similar to the transition states TS11 and TS12 for the H-abstraction reaction from CH<sub>3</sub>OH by ClO radical. At M06-2X/cc-pVTZ, the O<sub>1</sub>-H<sub>0</sub> bond is 75 extended by 0.229 Å (= 24 %) in TS21 when compared to  $O_1$ - $H_0$ bond in isolated CH<sub>3</sub>OH molecule and the bond length H<sub>0</sub>-O<sub>2</sub> is greater by 0.192 Å (= 20 %) from the HOCl molecule. The C- $H_1$ and H<sub>1</sub>-O<sub>2</sub> bonds in TS22 at M06-2X/cc-pVTZ are 1.224 Å and 1.341 Å respectively. Thus in TS22, the increase in C-H<sub>1</sub> bond is 80 0.130 Å (= 12 %) than C-H<sub>1</sub> bond in the isolated CH<sub>3</sub>OH molecule and elongation in forming  $H_1$ - $O_2$  bond is by 0.377 Å (= 39 %) comparative to H<sub>1</sub>-O<sub>2</sub> bond in HOCl molecule. The extent of C-O<sub>1</sub> bond shortening in TS21 and TS22 is similar as in TS11 and TS12. The bond angle  $\theta(O_1-H_0-O_2)$  is 164.7° in TS21 and <sub>85</sub>  $\theta$ (O<sub>2</sub>-H<sub>1</sub>-C) is 168.3<sup>0</sup> in TS22 were obtained at M06-2X/ccpVTZ. These bond angles reflect that the attack of BrO on hydroxyl H-atom or on methyl H-atom of CH3OH is not collinear.

From the potential energy surface of CH<sub>3</sub>OH+BrO 90 reaction, it is noticed that the TS is connected to the loosely bound PreM in the backward direction and PostM in the forward direction. It can be observed from the bonding density in Table 3, that the molecular complexes associated with CH<sub>3</sub>OH+BrO reaction are driven by the formation of intermolecular H-bonding 95 and halogen bonding. TS21 is the saddle point with pre-reactive complex CH<sub>3</sub>OH···OBr (PreM21) and post-reactive complex CH<sub>3</sub>O···HOBr (PostM21) for R3 reaction pathway while TS22 is connected to BrO···HCH2OH (PreM22) and BrOH···CH2OH (PostM12) for R4 pathway. Geometric parameters of the PreMs 100 are close to CH<sub>3</sub>OH and BrO and parameters for PostMs are related to isolated HOCl and CH<sub>3</sub>O radical (PostM21) or CH<sub>2</sub>OH radical (PostM22). At the entrance channel, the intermolecular distance H<sub>0</sub>-O<sub>2</sub> is 2.115 Å in PreM21 and H<sub>1</sub>-O<sub>2</sub> distance is 2.569 Å in PreM22 as obtained at M06-2X/cc-pVTZ. On the other 105 hand, at the exit channel, the intermolecular O<sub>1</sub>-H<sub>0</sub> bond distance is 1.862 Å in PostM21 and C-H<sub>1</sub> bond distance is 2.150 Å in PostM22. The H<sub>0</sub>-O<sub>2</sub> bond density is 0.018 au in PreM21 and H<sub>1</sub>-O<sub>2</sub> density is 0.008 au in PreM22. The second intermolecular Br-O<sub>1</sub> bond distance is 3.217 Å in PreM22 and is 3.253 Å in TS22 and both stationary points have density of 0.010 au.  $O_1$ - $H_0$  bond density is again found to be 0.032 au in PostM21 and C-H<sub>1</sub> bond density is 0.021 au in PostM22. In PostM22, second H-bond, Br-H<sub>0</sub> is present with distance 2.751 Å and density 0.011 au. At M06-2X/cc-pVTZ, level of theory the calculated bond angle 115  $\theta(O_1-H_0-O_2)$  for PreM21 and PostM21 are 143.8° and 156.6° respectively, and  $\theta(O_2-H_1-C)$  for PreM22 is 107.9° and for

PostM22 is  $153.5^{\circ}$ . The dihedral angle  $\phi(Br-O_2-H_0-O_1)$  for the molecular complexes following R3 path are 30.6° in PreM21 complex and is 54.3° in PostM21 complex. For the reaction CH<sub>3</sub>OH+BrO following R4 path, the dihedral angle  $\phi$ (Br-O<sub>2</sub>-H<sub>1</sub>-<sub>5</sub> C) is 52.1° for the pre-reactive molecular complex PreM22 and 15.2° for the post-reactive molecular complex PostM22. **3.2.** Energetics: The different kinetic and thermodynamic parameters for all the species involved in CH<sub>3</sub>OH+ClO (R1, R2) and CH<sub>3</sub>OH+BrO (R3, R4) reactions at CCSD(T)/cc-10 pVTZ//M06-2X/cc-pVTZ are given in Table 4 and 5. All these parameters are ZPE and spin-orbit corrected. Table 4 includes the adiabatic barrier height ( $\Delta E_0^{\#}$ ), enthalpy of activation ( $\Delta H_0^{\#}$ ), Gibbs free energy of activation ( $\Delta G_0^{\#}$ ), enthalpy of reaction (  $_{r}\Delta H_{0}$ ), reaction free energies ( $_{r}\Delta G_{0}$ ), entropy ( $\Delta S_{0}$ ) and total 15 potential energies ( $_r\Delta E_0$ ) of products relative to the reactants in the reaction of CH<sub>3</sub>OH with XO (X=Cl, Br) radical calculated at 298.15 K. The reaction free energies of the hydroxyl Habstraction reaction from CH<sub>3</sub>OH by both ClO (R1) and BrO (R3) radicals show that these pathways are endergonic reaction  $_{20}$  ( $\Delta G > 0$ ). In Table 4, the calculated free energies of the reactions proceeding through R2 and R4 pathways for the methyl Habstraction reaction from CH<sub>3</sub>OH by ClO and BrO radicals are -0.47 kcal/mol and -1.60 kcal/mol and thus these are exergonic reaction (ΔG < 0). At 298.15 K, reactions following R1, R2 25 pathways with ClO radical are endothermic along with the R3 reaction pathway with BrO radical ( $\Delta H > 0$ ). The reaction enthalpy for the methyl H-abstraction by BrO radical (R4) CCSD(T)/cc-pVTZ//M06-2X/cc-pVTZ calculated at exothermic by a slight negative value of 0.47 kcal/mol. 30 adiabatic barrier height,  $\Delta E_0^{\#}$  calculated at CCSD(T)/ccpVTZ//M06-2X/cc-pVTZ for all the pathways R1, R2, R3 and R4 including spin-orbit and ZPE correction are reported in Table 4. This barrier height is found to be positive for both the possible Habstraction pathways with ClO and BrO radicals. In Table 4, 35 CCSD(T)/cc-pVTZ//M06-2X/cc-pVTZ computed barrier height relative to reactants are 13.31 kcal/mol, 8.81 kcal/mol, 12.52 kcal/mol and 8.35 kcal/mol for R1, R2, R3 and R4 respectively. From these barrier heights it may be gleaned that the reactions for hydroxyl H-abstraction (R1, R3) have higher barrier height than 40 the methyl H-abstraction pathways (R2, R4). Table 5 reports the kinetic and thermodynamic parameters for the pre-reactive molecular complexes (PreM11, PreM12, PreM21, PreM22) and post-reactive molecular complexes (PostM11, PostM12, PostM21, PostM22) computed at CCSD(T)/cc-pVTZ//M06-45 2X/cc-pVTZ and 298.15 K. The XO (X=Cl, Br) radical approaches CH<sub>3</sub>OH for either hydroxyl or methyl H-abstraction and form weak bonded intermolecular PreM complexes which are more stabilized than the reactants by an amount of 2.06 kcal/mol (PreM11), 1.11 kcal/mol (PreM12), 3.16 kcal/mol (PreM21) and 50 1.59 kcal/mol (PreM22). Post-reactive molecular complexes for R1 (PostM11) and R3 (PostM21) reactions show less stability when compared to reactants and for R3 (PostM12) and R4 (PostM22) are more stable than the reactants. At CCSD(T)/ccpVTZ//M06-2X/cc-pVTZ all the post-reactive complexes on each 55 potential energy surfaces are more stable than the products. From Figure 2 and 3, it is observed that the TSs are above the prereactive and post-reactive molecular complexes on the potential

pVTZ for CH<sub>3</sub>OH+ClO  $(k_{RI}, k_{R2})$  and CH<sub>3</sub>OH+BrO  $(k_{R3}, k_{R4})$ reactions computed at different temperature within the range 200-2500 K. From Table 6, it can be observed that the rate constants,  $k_{R2}$  and  $k_{R4}$  for methyl H-abstraction from CH<sub>3</sub>OH leading to 65 hydroxymethyl (CH2OH) radical formation shows larger rate constant than rate constants,  $k_{RI}$  and  $k_{R3}$  for hydroxyl Habstraction forming methoxy (CH3O) radical for the studied temperature for both ClO and BrO radicals. temperatures ( < 1000 K) formation of CH<sub>3</sub>O radical from 70 CH<sub>3</sub>OH is negligible for both ClO and BrO radicals which is more pronounced in case of ClO radical. Due to the presence of upward curvature, the calculated CVT rate constants were fitted to the modified three parameter Arrhenius equation of the type  $k(T) = AT^n \exp(-E_a/RT)$  rather than two parameter Arrhenius 75 equation and the plots are shown in Figure 4 and in Table 7, the fitted Arrhenius parameters A, n and  $E_a$  for all four reactions: R1, R2, R3, R4 are given. The fitted Arrhenius equations in units of cm³molecule-1s-1 for CH<sub>3</sub>OH+XO (X=Cl, Br) reactions are

80  $k_{p,l}(T) = 4.55 \text{ x} 10^{-20} T^{1.70} \exp(-4091/T)$  $k_{p,2}^{(T)}(T) = 7.37 \text{ x} 10^{-19} T^{1.54} \exp(-2097/T)$  $k_{p,2}(T) = 7.39 \times 10^{-23} T^{2.74} \exp(-2093/T)$  $k_{Rd}(T) = 1.74 \times 10^{-20} T^{2.38} \exp(-2217/T)$  $k_{ovl}^{-1}(T) = 3.92 \text{ x} 10^{-19} T^{1.63} \exp(-2062/T)$ 85  $k_{\text{ov}}^{(7)}(T) = 1.53 \text{ x} 10^{-20} T^{2.41} \exp(-2206/T)$ 

In CH<sub>3</sub>OH, the C-H bond strength (= 94 kcal/mol) is lower than the O-H bond strength (= 104 kcal/mol).<sup>36</sup> For the temperature range under investigation, the H-abstraction from methyl group is 90 dominated over the H-abstraction from hydroxyl group of CH<sub>3</sub>OH by ClO and BrO radicals. The overall rate constant  $k_{ovI}$  $(=k_{RI}+k_{R2})$  and  $k_{ov2}$   $(=k_{R3}+k_{R4})$  are also reported in Table 6. At higher temperatures ( > 1000 K), hydroxyl H-abstraction reaction has some contribution towards the overall rate constants. The 95 branching ratio (\$\phi\$), which is defined as the ratio for a particular pathway rate constant divided by the sum of rate constants for all parallel reaction pathways are also included in Table 6 and the plots are shown in Figure 5. These branching ratios are used to emphasize the importance of one pathway over the other one. It 100 is necessary to know the branching ratio which is the indicator of preference of a pathway at different temperatures. At low temperature, the branching ratio for the reaction formation of CH<sub>2</sub>OH product radical is 100% with ClO radical. As the temperature increases, the reaction pathway contribution from 105 CH<sub>3</sub>O product-radical formation reaction also increases. With the BrO radical, the branching ratio value for CH<sub>2</sub>OH product radical formation is found to be more than 90% at all temperatures for the entire temperature range studied. We have compared our results of studied reaction with the H-abstraction 110 reaction from CH<sub>3</sub>OH by OH, Cl and Br radicals available in literature. For the H-abstraction reaction from CH<sub>3</sub>OH by hydroxyl (OH) radical, the rate constant following methyl Habstraction was found to be dominant at low temperature over the hydroxyl H-abstraction reaction. 37,38 As temperature rises, the 115 hydroxyl H-abstraction rate constant also becomes important. This is also consistent with the H-abstraction reaction of CH<sub>3</sub>OH+Cl but for the reaction CH<sub>3</sub>OH+Br, the rate constant for methoxy radical formation pathway is found to be inactive even at higher temperature. 39,40 Our results for H-abstraction with 120 ClO and BrO radicals are also similar to the reaction with OH, Cl, Br radical where hydroxymethyl radical forms predominantly. A comparision plot for the reactivity of OH, Cl, Br, ClO and BrO

3.3. CH<sub>3</sub>OH+XO (X=Cl, Br) reaction kinetics: Table 6 reports

60 the fitted rate constant data at CCSD(T)/cc-pVTZ//M06-2X/cc-

energy surface for all pathways.

for the H-abstraction from CH<sub>3</sub>OH is shown in Figure 6. Among these radicals in Figure 6, it is observed that Cl radical shows the highest rate constant for the methyl H-abstraction from CH<sub>3</sub>OH and thus the overall rate constant. The hydroxyl H-abstraction 5 rate constant is found to be more for OH than other radicals but the overall rate constant for OH is lower than Cl radical. It is because of higher contribution from methyl H-abstraction to the overall by Cl than OH. Cl forms barrierless transition state<sup>40</sup> for methyl H-abstraction and thus contributes more to the overall rate 10 constant than OH. Kinetically, H-abstraction from CH<sub>3</sub>OH by Cl or Br radicals are more favourable than XO (X=Cl, Br) radicals where H-abstraction involved O-atom of XO radicals. Substitution of H-atom of OH radical by halogen atoms makes it less reactive than either OH or X radicals. Where Cl shows 15 larger rate of H-abstraction reaction than Br radical, ClO has lower rate constant value than BrO over the studied temperature range. For methyl H-abstraction reaction and overall rate of the CH<sub>3</sub>OH+Cl shows a noticeable difference from CH<sub>3</sub>OH+Br reaction. At lower temperature this difference is 20 higher and as temperature increases the difference becomes smaller. From Figure 6, it is observed that the methyl Habstraction and overall rate of the reaction shows smaller difference at lower temperatures in case of reaction of ClO and BrO when compared to the reaction of Cl and Br. Temperature 25 has less effect on methyl H-abstraction by Cl radical due to the barrierless transition state but has more effect on the reaction of OH, Br, ClO and BrO radicals. Indeed, as temperature increases there is an increase in rate also. Experimental study on CH<sub>3</sub>OH+XO (X=Cl, Br) is not known, there is available 30 experimental data for the H-abstraction reaction from CH<sub>3</sub>OH by OH or halogen radicals using different experimental techniques like fast flow or laser photolysis-resonance fluorescence. 37,39,41 The experimental study of CH<sub>3</sub>OH+XO (X=Cl, Br) reaction can be attempted using these techniques and the present study will be 35 helpful for analyzing the branching ratio of methoxy or hydroxymethyl radical formation at different temperature.

## 5. Conclusion

40 The kinetic and mechanism study of the two channel Habstraction reaction of CH<sub>3</sub>OH+XO (X=Cl, Br) was performed with the use of M06-2X and CCSD(T) level of theory combined with cc-pVTZ basis set. Pre-reactive and post-reactive molecular complexes were located at entrance and exit channel, respectively CH<sub>3</sub>OH+ClO (CH<sub>3</sub>O+HOCl (R1),CH<sub>3</sub>OH+ClO  $(CH<sub>2</sub>OH+HOC1 (R2), CH<sub>3</sub>OH+BrO \rightarrow CH<sub>3</sub>O+HOBr (R3) and$ CH<sub>3</sub>OH+BrO → CH<sub>2</sub>OH+HOBr (R4) reactions. The potential energy surface of R1, R2, R3 and R4 reactions were obtained at CCSD(T)/cc-pVTZ//M06-2X/cc-pVTZ. The rate constants for 50 all the reactions were calculated using canonical variational transition state theory with unsymmetrical Eckart tunneling correction. The calculated rate constants were fitted to modified three parameters Arrhenius equation for all the reaction pathways. At CCSD(T)/cc-pVTZ//M06-2X/cc-pVTZ, the rate 55 constant associated with the hydroxymethyl radical formation was found to be higher than the methoxy radical formation reaction for both ClO and BrO radicals for the entire temperature range of 200-2500 K. The importance of formation of one product over the other was analyzed by calculating the branching 60 ratio.
