This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. This Accepted Manuscript will be replaced by the edited, formatted and paginated article as soon as this is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
Three-dimensionally ordered macroporous SiO$_2$-supported transition metal oxide catalysts: Facile synthesis and high catalytic activity for diesel soot combustion

Abstract

Three-dimensionally ordered macroporous (3DOM) SiO$_2$ was synthesized by colloidal crystal template (CCT) method, and 3DOM SiO$_2$-supported transition metal oxides catalysts were prepared by facile incipient-wetness impregnation method. The as-prepared catalysts show well-defined three-dimensionally ordered macroporous structures. The transition metal oxides formed different sizes of nanoparticles and loaded on the 3DOM SiO$_2$. The as-prepared catalysts show high catalytic activities for soot combustion. Among the studied catalysts, 3DOM MnO$_x$/SiO$_2$ catalyst (molar ratio of Mn to Si is 1:4) shows the highest catalytic activity among the studied catalysts, e.g. $T_{10}$, $T_{50}$ and $T_{90}$ are 297, 355 and 393 $^\circ$C, respectively, and $S^m_{CO_2}$ is 95.5%. The catalytic performance of 3DOM SiO$_2$-supported transition metal oxide catalysts are mainly controlled by three factors: the macroporous effects of 3DOM structure, the redox properties of transition metal oxides and the sizes of transition metal oxides NPs. 3DOM SiO$_2$-supported transition metal oxide catalysts are promising for practical applications in soot combustion owing to high activity and low cost.

Keywords: Three-dimensionally ordered macroporous (3DOM) catalysts; SiO$_2$; transition metal oxide; catalytic activity; soot combustion
1 Introduction

Nowadays, toxicological and epidemiological studies indicate that soot particles of diesel exhaust are threatening the environment and people’s health.¹ A great number of illness, which include irritation of the eyes, throat vomiting, light-headedness, headache, heartburn, bronchitis, lung cancer or even premature death and so on, have been triggered by soot particles.² In addition, soot particles are also a main source of urban atmospheric particulate matters (PM2.5).³ A lot of previous works demonstrated that the exhaust of diesel engine is one of the largest contributors to soot particles in the most large and medium-sized cities. Therefore, elimination of diesel engine exhaust (especially for soot particles) is urgent for development of society and economy.⁴ Indeed, great efforts have been made to reduce the soot particles to meet the stringent environmental regulations and protect human health.⁵ Researches indicate that the after-treatment of diesel exhaust is one of the most perspective techniques, and the catalyst is one of important controlling factors for soot elimination.⁶,⁷ Therefore, the development of novel catalyst is one of the most important tasks for elimination of soot particles.

A number of catalysts have been studied for soot combustion at low temperatures, including noble metals⁸, perovskite-type oxides⁹, CeO₂-based oxides¹⁰,¹¹, etc. Since it is a gas-solid-solid reaction for catalytic soot combustion, it is affected by two factors, the contact efficiency between soot and catalyst, and the intrinsic activity of catalyst. Because traditional catalysts show smaller pore sizes (<10 nm) than soot particles
 (>20 nm), soot particles are difficult to enter the inner pores of these catalysts.\textsuperscript{12}

Recently, three-dimensionally ordered macroporous materials with uniform pore size
(>50 nm) and well-defined structure have been applied in the field of heterogeneous
catalysis.\textsuperscript{13-15} Due to ordered macroporous structures, soot particles could easily enter
their inner pores, and thus they flexibly access the active sites. A series of 3DOM
metal mixed oxides, including La\textsubscript{1-x}K\textsubscript{x}CoO\textsubscript{3}\textsuperscript{16} and Ce\textsubscript{1-x}Zr\textsubscript{x}O\textsubscript{2}\textsuperscript{17} and so on, have been
prepared in our group, and they all show better catalytic performances than
corresponding nanoparticle catalysts for soot oxidation. The intrinsic activity of
catalyst is another factor for enhancing catalytic activity after resolving the contact
efficiency. To further improve the intrinsic activity of catalysts, our group have
prepared a series of 3DOM oxides-supported Au or/and Pt catalysts.\textsuperscript{18-22} Those
catalysts all exhibit super high catalytic activities for soot combustion. However, due
to the limited resources, noble metal catalysts are very expensive than metal oxide
catalysts, which restricts the extensive application of noble metal catalysts.

In the past decades, low-cost catalysts, including single metal oxides, mixed metal
oxides, perovskites, spinels, alkali earth metals and alkali metals, etc. showed high
catalytic activity for soot combustion.\textsuperscript{23-26} As always, nano-catalysts have been used in
the field of catalysis and they show excellent catalytic activities in many reactions
especially for oxidation reactions.\textsuperscript{27-29} Therefore, the nano-catalysts are also expected
to exhibit high catalytic activities for soot combustion.\textsuperscript{31,32} However, design and
preparation of low cost catalysts to combine nano-effect and macroporous effect are
promising for increasing of catalytic activity for soot combustion and practical
application. Researchers have demonstrated that transition metal oxides with changing valence states display excellent redox properties when they are applied in the oxidation reactions.\textsuperscript{33-36} Based on the above reasons, transition metal oxides nanoparticles (NPs) supported on 3DOM SiO\textsubscript{2}, are expected to enhance catalytic performance for soot combustion by making the best of nano-effect and macroporous effect in 3DOM SiO\textsubscript{2}-supported transition metal oxide catalysts.

In this paper, 3DOM SiO\textsubscript{2} support was synthesized by colloidal crystal template (CCT) method. 3DOM SiO\textsubscript{2}-supported transition metal oxide catalysts were prepared by incipient wetness impregnation method. The physical and chemical properties of as-prepared catalysts were characterized by means of X-ray diffraction (XRD), scanning electron microscopy (SEM), transmission electron microscopy (TEM), temperature-programmed reduction with H\textsubscript{2} (H\textsubscript{2}-TPR) measurements, UV-Vis diffuse reflectance spectra (DRS) and X-ray photoelectron spectra (XPS) etc. The catalytic performances of as-prepared catalysts were evaluated for soot combustion, and the effects of different transition metal oxide on the catalytic activities for soot combustion were investigated.

2 Experimental

2.1 Catalysts preparation

2.1.1 Synthesis of highly well-defined PMMA microspheres

The synthesis of monodispersed PMMA (polymethyl methacrylate) microsphere and the assembly template are similar to that described previously\textsuperscript{32}. Detailed procedures are described in supporting information.
2.1.2 Synthesis of 3DOM SiO$_2$

3DOM SiO$_2$ was synthesized by colloidal crystal template (CCT) method with PMMA arrays as template and using tetraethyl orthosilicate (TEOS) as precursors. In a typical procedure, 4.6 g TEOS was dissolved into the mixture of water (2.5 mL), alcohol (5 mL) and HCl aqueous solution (2mol/L, 2.5 mL). After that, the hydrolyzation was proceeded in a water bath at 35 °C for 4 h. Then, 3g PMMA arrays were added into the above solution for impregnation. After complete impregnation, the PMMA arrays with the precursor solution were separated by vacuum filter and dried at 30 °C for 24 h. The dried samples were calcined to remove the CCT in a tube furnace with an air flow (80 mL min$^{-1}$). The temperature-rising rate was 1 °C min$^{-1}$ from room temperature to 600 °C, and the temperature of calcination at 600 °C was kept for 4 h, and then 3DOM SiO$_2$ supports were obtained.

2.1.3 Synthesis of 3DOM SiO$_2$-supported transition metal oxide catalysts

3DOM SiO$_2$-supported transition metal oxide catalysts were prepared by incipient-wetness impregnation method. In a typical procedure, a certain amount of transition metal nitrates (50 wt% Mn(NO$_3$)$_2$ aqueous solution, Fe(NO$_3$)$_3$·9H$_2$O, Co(NO$_3$)$_2$·6H$_2$O, Ni(NO$_3$)$_2$·6H$_2$O, Cu(NO$_3$)$_2$·3H$_2$O) were dissolved into deionized water, and then the above aqueous solution was added into 3DOM SiO$_2$. After that, the impregnated sample was dealt with ultrasonic for 10 min and dried at 80 °C for 24 h. Then, the sample was calcined at 550 °C for 4 h in tube furnace and 3DOM SiO$_2$-supported transition metal oxide catalysts were obtained. The stoichiometric ratios of raw materials for 3DOM SiO$_2$-supported transition metal oxide catalysts are
listed in the Table 1. In addition, different loading amounts of manganese nitrate on 3DOM SiO$_2$ were also prepared and the corresponding dosages of raw materials are also listed in the Table 1.

2.2 Physical and chemical characterization

XRD patterns were measured on a powder X-ray diffractometer (Bruker D8 Advance) using CuKα (k=0.15406 nm) radiation with a Nickel filter operating with voltage and current of 40 kV and 40 mA in the 2θ range of 10-90$^\circ$ at a scanning step of 0.02$^\circ$. The patterns were compared with JCPDS reference data for phase identification. The surface morphology of the catalyst was observed by field emission scanning electron microscopy (FESEM) on a Quanta 200F instruments using accelerating voltages of 5 kV. SEM samples were dusted on conducting resin and coated with 10 nm Au prior to measurement. The TEM images were obtained using a JEOL JEM-2100 transmission electron microscope. A typical TEM sample was prepared by adding several droplets of a nanoparticles/ethanol mixture onto a carbon-coated copper grid. Nitrogen adsorption/desorption isotherms at -196 °C were recorded using a Micromeritics TriStar II 3020 porosimetry analyzer. The samples were degassed at 300 °C for 4 h prior to the measurements.

H$_2$-TPR was performed using a Quantachrome Autosorb-iQ, USA. A sample of 100 mg was loaded into a U-shaped quartz reactor and pre-treated in Ar at 300 °C for 1 h. After cooling to room temperature, the flow gas was switched to 10-vol% H$_2$/Ar, and the catalyst was heated to 900 °C at a rate of 10 °C min$^{-1}$. The flow rate of 10-vol% H$_2$/Ar is 50 mL min$^{-1}$. The consumption of hydrogen was recorded by thermal
conductivity detector (TCD). Calibration of the instrument was carried out with CuO of known amount. X-ray photoelectron spectra (XPS) were recorded on a Perkin-Elmer PHI-1600 ESCA spectrometer using Mg Kα X-ray source. The binding energies were calibrated using C1s peak of contaminant carbon (BE = 284.6 eV) as an internal standard.

2.3 Activity measurements

The catalytic performances of all catalysts were evaluated with a temperature-programmed oxidation reaction (TPO) on a fixed-bed tubular quartz reactor (Φ= 8 mm), and each TPO run from 150 to 650 °C at a 2 °C min⁻¹ rate. The model soot was Printex-U particulates (diameter 25 nm, purchased from Degussa). The catalyst (100 mg) and soot (10 mg) were mixed at a weight ratio of 10:1 with a spatula in order to reproduce the loose contact mode. Reactant gases (50 mL min⁻¹) contain 10% O₂ and 0.2% NO balanced with Ar. The outlet gas compositions were analyzed with an on-line gas chromatograph (GC, Sp-3420, Beijing) by using FID detectors. Before entering the FID detector, CO and CO₂ were fully converted to CH₄ by a convertor with Ni catalyst at 380 °C. The catalytic activity was evaluated by the values of T₁₀, T₅₀ and T₉₀, which were defined as the temperatures at 10%, 50% and 90% of soot conversion, respectively. The selectivity to CO₂ formation (S_{CO₂}) was defined as that the CO₂ outlet concentration (C_{CO₂}) divided by the sum of the CO₂ and CO outlet concentration, i.e., S_{CO₂} = C_{CO₂}/(C_{CO} + C_{CO₂}). S_{CO₂}^m was denoted as S_{CO₂} at the maximum temperature corresponding to the soot-burnt rate was the highest. In all TPO experiments, the reaction was not finished until the soot was completely burnt.
3 Results and discussion

3.1 Catalyst characterization

3.1.1 The results of XRD

XRD patterns of 3DOM SiO$_2$-supported transition metal catalysts are shown in Figure 1. As shown in Figures 1a-g, different transition metal catalysts exhibit various diffraction peaks. For the pure SiO$_2$ (Figure 1a), a broad peak at 2θ of 23.5° can be observed, which is typical peak of amorphous silica.$^{37}$ An overview of the XRD patterns of as-prepared 3DOM transition metal catalysts in Figures 1b-f indicates that transition metal oxides formed after the process of calcination. The detailed explanations about 3DOM SiO$_2$-supported transition metal catalysts are shown in the Supplementary Information. In addition, from the Figures 1b-f, it can be seen that the peak of amorphous silica disappeared when transition metal oxides were supported on the surface of 3DOM SiO$_2$. The XRD patterns of 3DOM SiO$_2$-supported MnO$_x$ catalysts with different MnO$_x$ loading amounts are shown in Figures 1g-j. With the increasing of MnO$_x$ loading amount, the intensity of diffraction peaks of amorphous SiO$_2$ becomes weaken and some feature peaks of manganese oxide appear and their intensities enhance. As shown in Figures 1i-j, the diffraction peaks of SiO$_2$ almost disappear when the loading amount of MnO$_x$ is over a certain value (molar ratio of Mn to Si is over 1:4). It is attributed to MnO$_x$ coated on the surface of 3DOM SiO$_2$.

3.1.2 The results of SEM

Figure 2 shows the SEM images of 3DOM SiO$_2$-supported transition metal
catalysts with loading of different transition metals. The SEM images show that the
macropores with average diameter of ca. 310±20 nm are interconnected through open
windows, ca. 90-140 nm in diameter, and the wall thicknesses are ca. 30-50 nm. As
shown in the Figures 2a-f, it can be seen that the macropores have uniform pore sizes,
windows and wall thicknesses, and those macropores are highly periodically arrayed
and interconnected through small windows. These SEM images clearly demonstrate
that all 3DOM samples have long range ordered macroporous structure. As shown in
the inserted SEM images, some dark dots in macropores were visible clearly. The
SEM images suggest that the process of supporting transition metal oxides on 3DOM
SiO$_2$ has no influence on 3DOM structure.

Figure 3 shows the SEM images of 3DOM SiO$_2$-supported MnO$_x$ catalysts with
different MnO$_x$ loading amounts. From the Figure 3 and Figure 2b, it can be seen that
3DOM structure is clearly observed when the ratio of Mn to Si is lower than 1:4
(Figures 3a,b and Figure 2b), while 3DOM structure has a little destruction when the
molar ratio of Mn to Si is over 1:4 (Figures 3c,d). The reason for the result may be
that the excess MnO$_x$ agglomerated and formed big particles. 3DOM structure of SiO$_2$
is affected by the big particles. From the all SEM images with different MnO$_x$
loading amounts, it can be concluded that 3DOM structure can be maintain when
MnO$_x$ loading amount is lower than a certain constant (molar ratio of Mn to Si is 1:4).

3.1.3 The results of TEM

TEM images of 3DOM SiO$_2$-supported transition metal catalysts with loadings of
different transition metals are shown in Figure 4. From the Figure 4a, it can be seen
that 3DOM SiO$_2$ with over-lapped pores can be clearly observed by TEM image. No granular or spherical SiO$_2$ are observed on the surface of 3DOM SiO$_2$. Combined with XRD result of SiO$_2$ (Figure 1a), it indicates that the framework of 3DOM SiO$_2$ was accumulated by amorphous SiO$_2$. As shown in Figures 3b, c, the surface of 3DOM SiO$_2$ is successfully decorated with well-dispersed MnO$_x$ and Fe$_2$O$_3$ nanoparticles (NPs), and no larger agglomerated particles is observed. The MnO$_x$ NPs with particle size of 10-30 nm and Fe$_2$O$_3$ NPs with particle size of 4-13 nm are adhered on the walls of 3DOM SiO$_2$. The average MnO$_x$ and Fe$_2$O$_3$ NPs sizes are estimated to be 23.5±3.6 and 8.6±2.4 nm for 3DOM MnO$_x$/SiO$_2$ and Fe$_2$O$_3$/SiO$_2$ catalysts, respectively. And the particle size of Co$_3$O$_4$ NPs on 3DOM Co$_3$O$_4$/SiO$_2$, which the average value is about 60 nm in Figure 4d, is much bigger than 3DOM MnO$_x$/SiO$_2$ catalysts. The TEM image (Figure 4e) of NiO/SiO$_2$ catalyst shows that NiO NPs are supported on the surface of 3DOM SiO$_2$, while the particle size of NiO NPs is located in the range of 20-50 nm. This large particle size is disadvantageous to the catalytic activity of catalyst. TEM image of CuO/SiO$_2$ (Figure 4e) shows that the part of dark place is bulk CuO, indicating that bulk CuO formed in the process of calcination. The SEM (Figure 2) and TEM (Figure 4) images of 3DOM SiO$_2$-supported transition metal catalysts suggest that 3DOM structure of SiO$_2$ well maintains and the transition metal oxides exhibit different particle sizes with different transition metal elements.

Figure 5 shows the TEM images of 3DOM SiO$_2$-supported MnO$_x$ catalysts with different MnO$_x$ loading amounts. From Figures 5a,b and Figure 4b, it can be seen that the surface of 3DOM SiO$_2$ is successfully decorated with well-dispersed MnO$_x$ NPs
and no larger agglomerated particles is observed when molar ratio of Mn to Si is less than 1:4. The MnOx NPs with particle size of 10-30 nm are adhered on the walls of 3DOM SiO2. However, the particle size of MnOx NPs increases with increasing of MnOx loading amount. The particle sizes of MnOx particles are about 50 nm and 150 nm for MnOx/SiO2 when molar ratios of Mn to Si are 1:3 and 1:2. It is attributed to that the concentration of impregnation liquid (Mn(NO3)2 aqueous solution) become higher and higher with the increasing of molar ratio of Mn to Si. As shown in the Figure 5d, most of MnOx particles are supported on outside surface of 3DOM SiO2 and no small MnOx particles can be observed on the inner surface of 3DOM SiO2. This agglomeration of active component of MnOx/SiO2 catalyst may lead to low catalytic activity for soot combustion when molar ratio of Mn to Si is 1:2.

3.1.4 The results of BET

Nitrogen adsorption-desorption isotherms for 3DOM SiO2-supported transition metal catalysts were tested and the results are shown in Figure 6. The as-prepared catalysts exhibit similar adsorption-desorption isotherm shapes. However, their hysteretic loops are different when different transition metals support on 3DOM SiO2. As shown in Figure 6a and b, 3DOM SiO2 and 3DOM SiO2-supported MnOx catalyst show obvious hysteretic loops, while the others exhibit small hysteretic loops. The values of surface area, total pore volume and pore size are listed in the Table 2. 3DOM SiO2 shows the highest surface area among the as-prepared 3DOM catalysts and its value is 270.1 m²/g. The scraggly surface of 3DOM SiO2 may contribute to enhancing the surface area owing to no nanoparticles on the surface. In addition,
3DOM SiO$_2$ shows the lowest pore size among the as-prepared catalysts. The surface area obviously decreased when transition metals supported on 3DOM SiO$_2$. As shown in the Table 2, the order of surface area value for as-prepared catalysts is as follows: Fe$_2$O$_3$/SiO$_2$ > MnO$_x$/SiO$_2$ > NiO/SiO$_2$ > Co$_3$O$_4$/SiO$_2$ > CuO/SiO$_2$. Combined with the TEM images in Figure 4, the reason for this order can be explained by the size of transition metals nanoparticles. In other words, small nanoparticles will contribute to enhancing the surface area owing to high surface area of small NPs. The total pore volume and pore size of as-prepared catalysts are different with the different transition metals. 3DOM SiO$_2$ shows the highest total pore volume and pore size among the as-prepared catalysts. From the results of SEM and TEM, it can be seen that the pore sizes of as-prepared catalysts are more than 300 nm. However, as shown in the Table 2, the pore sizes of as-prepared catalysts are less than 10 nm. The reason for this phenomenon is that the value of pore size (based on BET results) is calculated by BJH desorption average pore diameter. This calculation method does not contain the macropores. Therefore, the pore sizes (based on BET results) of as-prepared catalysts are less than 10 nm.

### 3.1.5 The results of UV-Vis diffuse reflectance spectra

The UV-Vis DRS of 3DOM SiO$_2$-supported transition metal catalysts were obtained at room temperature in the range of 200-800 nm. From the Figure 7a, it can be seen that pure 3DOM SiO$_2$ has almost no absorption in the ultraviolet and visible region.$^{38}$ As shown in Figure 7b and 8g-j, the relative UV-Vis absorption spectrum of MnO$_x$/SiO$_2$ indicated the multivalent oxidation states of Mn. Combined with the XPS
results, the peaks in the range of 200-350 nm range could be reasonably assigned to \( \text{O}^{2-} \rightarrow \text{Mn}^{3+} \) charge transfer transitions in the \( \text{MnO}_x \). While the broad peak at 450 nm was ascribed to the d-d electron transitions of \( \text{Mn}^{3+} \) and \( \text{Mn}^{4+} \). From Figure 7c, it can be seen that the absorption of \( \text{Fe}_2\text{O}_3/\text{SiO}_2 \) was rapidly faded when wavelengths is longer than 560 nm. The broad absorption from 300 to 560 nm corresponds to the \( ^6\text{A}_1+^6\text{A}_1 \rightarrow ^4\text{T}_1(^4\text{G})+^4\text{T}_1(^4\text{G}) \) excitation of an \( \text{Fe}^{3+}-\text{Fe}^{3+} \) pair. The absorption at 200-300 nm is ascribed to the ligand to metal charge transfer transitions and partly contributed from the \( \text{Fe}^{3+} \) ligand field transitions \( ^6\text{A}_1 \rightarrow ^4\text{T}_1(^4\text{P}) \). As shown in Figure 7d, the UV-Vis spectra exhibited three different absorbance edges at 200-300, 400-600 and 700-800 nm for \( \text{Co}_3\text{O}_4/\text{SiO}_2 \). The bands (\( \lambda < 500 \) nm) can be assigned to the \( \text{O}^{2-} \rightarrow \text{Co}^{2+} \) charge transfer process, while the band (\( \lambda > 700 \) nm) was due to the \( \text{O}^{2-} \rightarrow \text{Co}^{3+} \) charge transfer. The UV-Vis DRS of \( \text{NiO}/\text{SiO}_2 \) is reported in Figure 7e. The spectrum of \( \text{NiO}/\text{SiO}_2 \) shows a strong absorption in the UV region, similar to an absorption plateau with two predominant components at 240 and 300 nm, in agreement with literature data. The absorption spectrum of \( \text{CuO}/\text{SiO}_2 \) (Figure 7f) revealed several absorption bands. The band appeared in the 220-360 nm spectral range can be assigned to the charge transfer transition of the ligand \( \text{O}^{2+} \) to isolated metal center \( \text{Cu}^{2+} \) and the d-d transition in \( \text{CuO} \) particles. The signal appeared between 650-800 nm could be ascribed to the \( 2\text{E}_g \rightarrow 2\text{T}_{2g} \) spin-allowed transitions of \( \text{Cu}^{2+} \) in the distorted octahedral symmetry.

3.1.6 The results of \( H_2-TPR \)

It is well known that soot catalytic combustion is a complicated gas-solid
(soot)-solid (catalyst) three-phase reaction. The intrinsic redox properties of catalysts play a key role in the combustion of soot. In this work, the redox properties of catalysts were characterized by H$_2$-TPR measurements and the results are shown in the Figure 8. As shown in Figures 8a-f, the peak positions and types of 3DOM SiO$_2$-supported transition metal catalysts vary with different kinds of transition metal. From the H$_2$-TPR profile of 3DOM SiO$_2$ (Figure 8a), it can be seen that no reduction peak is observed, indicating that 3DOM SiO$_2$ exhibits none redox property. Figure 8b shows the H$_2$-TPR profile of MnO$_x$/SiO$_2$, two main reduction peaks with peak temperatures at 320 and 416 °C can be observed. Assuming that MnO is the final state in the reduction of Mn species.$^{44}$ The peak at 230-350 °C could be assigned to the reduction of MnO$_2$/Mn$_2$O$_3$ to Mn$_3$O$_4$, and the peak at 350-500 °C may be assigned to the reduction of Mn$_3$O$_4$ to MnO. The results indicate that substantial amount of Mn$^{4+}$ and Mn$^{3+}$ in MnO$_x$/SiO$_2$ catalyst can be reduced to Mn$^{2+}$ below 500 °C, which is consistent with the previous reports.$^{45}$ Figure 8c depicts the H$_2$-TPR profile of Fe$_2$O$_3$/SiO$_2$, two main peaks, whose peak temperatures are located at 351 and 523 °C, are characteristics of two reduction steps. The first peak may be assigned to the reduction of Fe$_2$O$_3$ to Fe$_3$O$_4$, whereas the second may be attributed to the transition from Fe$_3$O$_4$ to FeO. Besides the above two main peaks, a weak reduction peak located at 600 °C can be assigned to the reduction of Fe$_3$O$_4$ to FeO in the inner Fe$_2$O$_3$ nanoparticles. Due to small particle sizes and high dispersion of Fe$_2$O$_3$ NPs, the reduction temperatures are lower than previously reported works. Previous studies found that the reduction behavior of Co$_3$O$_4$ is highly dependent on the dispersion state.
of cobalt. Large particles of Co$_3$O$_4$ were usually reduced to metallic cobalt by a single step while nanoparticles often went through a two-step process.$^{46}$ As shown in the Figure 8d, two reduction peaks, of which a minor reduction peak at 329 °C and main reduction peak at 376 °C, are observed for Co$_3$O$_4$/SiO$_2$ catalyst owing to Co$_3$O$_4$ NPs with particle size of 60 nm. The two overlapped reduction peaks are corresponded to the reduction of Co$_3$O$_4$→CoO→Co.$^{47}$ Figure 8e shows the H$_2$-TPR profiles of NiO/SiO$_2$ catalyst. Two overlapped reduction peaks with two peak maxima at 350 °C and 415 °C are obtained, which are consistent with the reduction of two types of Ni$^{2+}$/Ni$^{3+}$ species to metallic nickel.$^{48,49}$ The H$_2$-TPR profile of CuO/SiO$_2$ is shown in Figure 8f. The minor shoulder reduction peak at 222 °C is assigned to reduction of dispersed copper oxide, while the main reduction peak at 281 °C is corresponded to reduction of CuO.$^{42,50}$ The different reduction peaks of 3DOM SiO$_2$-supported transition metal catalysts indicate that those catalysts may exhibit various catalytic activities for soot combustion. Figures 8g-j display the H$_2$-TPR profiles of 3DOM MnO$_x$/SiO$_2$ catalysts with different MnO$_x$ loading amounts. Two main reduction peaks can be obtained in Figures 8g-j. The peak temperatures increase with the increasing of MnO$_x$ loadings. The first and second reduction peak temperatures increase from 300 to 336 °C and from 417 to 456 °C, respectively, for the sample with molar ratio of Mn to Si from 1:16 to 1:2. The possible reason for this result is that particle size of MnO$_x$ increases with the increasing of MnO$_x$ loadings (Figure 5). In addition, the intensity of H$_2$ consumption peak also increases with the increasing of MnO$_x$ loading amounts. Based on the above results of H$_2$-TPR, transition metal
oxides show high redox property owing to different chemical valence states of transition metal. The catalytic activity is possibly associated with the changing capacity of varied oxidation states and with “oxygen mobility” in the oxide lattice. This property may contribute to the enhancement of catalytic activity for soot combustion.

3.1.7 The results of XPS

Figure 9Aa displays the XPS spectrum of Mn 2p for 3DOM MnOx/SiO2 catalysts. The Mn 2p spectrum is significantly broadened and showed some asymmetry towards both Mn 2p3/2 and Mn 2p1/2 peaks. The binding energies of the XPS Mn 2p3/2 peak are found to be in the range 639.0-645.0 eV. Two kinds of Mn species including Mn3+ (ca. 641.5 eV), and Mn4+ (644.5 eV) are presented on the surface of as-prepared catalysts. Meanwhile, the Mn 2p1/2 peak also shows two kinds of Mn species at BEs range of 650-657 eV. From Figure 9Ab, it can be seen that the Fe 2p spectrum of Fe2O3/SiO2 is split into 2p3/2 (710.6 eV) and 2p1/2 (724.1 eV) doublets due to the spin-orbit coupling. According to the previous reports, the remarkable features of Fe2O3/SiO2 in XPS spectrum is a characteristic of Fe3+ in Fe2O3. In addition, there is a satellite peak at 718.9 eV beside the main peak of Fe 2p3/2 at 710.9 eV, which is also an evidence for Fe3+ in Fe2O3. The XPS result of Fe2O3/SiO2 is also in good agreement with the XRD result. As shown in Figure 9Ac, two spin orbit components of Co (Co 2p3/2 at 779.6 eV and Co 2p1/2 at 795.1 eV) and two weak satellites at higher energy (786-790 and 800-805 eV) for both Co peaks are obtained. The BE difference between Co 2p1/2 and Co 2p3/2 peaks is 15.5 eV, and it is in agreement with previously
reported for Co$_3$O$_4$.\textsuperscript{52,53} The Ni 2p XPS spectrum (Figure 9Ad) shows two characteristic double peaks of Ni 2p$_{1/2}$ and Ni 2p$_{3/2}$. The additional peak located at around 879.2 eV and 860.8 eV are the satellite of Ni 2p$_{1/2}$ and Ni 2p$_{3/2}$.\textsuperscript{54} According to the literature, the satellite peaks of Ni 2p$_{1/2}$ and Ni 2p$_{3/2}$ indicate that Ni$^{3+}$ ions or Ni$^{2+}$-OH species is present in NiO/SiO$_2$. Here, the Ni$^{3+}$ only refers to a structure containing vacancies in the NiO but does not indicate an existence of Ni$_2$O$_3$ phase in NiO/SiO$_2$.\textsuperscript{55} Figure 9Ae shows the spin-orbit split of Cu 2p$_{1/2}$ and Cu 2p$_{3/2}$ at 954.6 eV and 934.5 eV, respectively. The gap between Cu 2p$_{1/2}$ and Cu 2p$_{3/2}$ is 20.1 eV, which is similar with the standard spectrum of CuO. The existence of satellite peaks (943.7 and 962.5 eV) is an indicator of the Cu$^{2+}$ ions, which is excluded the possibility of Cu$_2$O phase in CuO/SiO$_2$ catalyst.\textsuperscript{56}

The corresponding O 1s XPS spectra are present in Figure 9B. Three types of O species is defined as O-I, O-II and O-III. The O-I component located at 529.5 eV are ascribed to lattice oxygen ions bonded to transition metal cations.\textsuperscript{57} Because of different transition metals, the BEs of O-I have a small shift from 529.4 to 530.4 eV. The dominating O-II component at BEs 532.6~ 533.1 eV is obviously related to O$^{2-}$ species in SiO$_2$ (Si-O-Si environments).\textsuperscript{58} The minor O-III component located at ~535.1 eV may include contributions from Si-OH groups. As shown in Figure 9C, the values of BEs for Si 2p are changed with different transition metals. The Si 2p spectra of the catalysts (Figure 9C) are dominated by a peak centered at BEs of 103.0~103.6 eV, characteristic of Si$^{4+}$ in SiO$_2$. The reason for shifted BEs is that different transition metals change the chemical environment of Si-O-Si bands. In addition, as shown in
Table S1, the surface compositions of as-prepared catalysts are different with bulk composition. The surface oxygen ratios are higher than corresponding bulk oxygen ratios, indicates that as-prepared catalysts will exhibit high catalytic activity for soot combustion.

3.2 Activity test

3.2.1 Catalytic activities for soot combustion

The catalytic activities of 3DOM SiO$_2$-supported transition metal catalysts for soot oxidation were evaluated and the results are listed in Table 3. To compare the catalytic activities of as-prepared catalysts, the combustion reactions of pure soot and 3DOM SiO$_2$ were also estimated under the same reaction conditions. For the pure soot, the $T_{10}$, $T_{50}$ and $T_{90}$ are 482, 564 and 609 °C, respectively. The 3DOM SiO$_2$ also shows somewhat catalytic activity for soot combustion, and the $T_{10}$, $T_{50}$ and $T_{90}$ are 354, 503 and 550 °C, respectively. This result indicates that the 3DOM structure of SiO$_2$ can enhance the contact area between soot and reaction gas when the soot and SiO$_2$ are met. All the 3DOM SiO$_2$-supported transition metal catalysts show high catalytic activities for soot combustion. However, different SiO$_2$-supported transition metal catalysts exhibit various catalytic activities. Compared the values of $\Delta T_{10}$, $\Delta T_{50}$ and $\Delta T_{90}$ of 3DOM SiO$_2$-supported transition metal catalysts in the Table 3, 3DOM MnO$_x$/SiO$_2$ catalyst shows the highest catalytic activity for soot combustion, the $\Delta T_{10}$, $\Delta T_{50}$ and $\Delta T_{90}$ of are 173, 202 and 212 °C, respectively. These results suggest that MnO$_x$ is optimal choice for soot combustion in those transition metal oxides. In addition, 3DOM SiO$_2$-supported transition metal catalysts show much higher CO$_2$
selectivity for soot combustion than that of pure soot combustion, and the values are all surpassed 90%. The CO$_2$ selectivity value of 3DOM MnO$_x$/SiO$_2$ catalyst is as high as 95.5%. These experimental results suggest that 3DOM MnO$_x$/SiO$_2$ catalyst is promising catalysts for soot combustion. In order to more clearly describe the results of Table 3, the CO$_2$ concentration profiles for soot combustion over 3DOM SiO$_2$-supported transition metal catalysts were listed in the Figure S1. From Figure S1A, it can be seen that the CO$_2$ concentration profiles are corresponding to the results of Table 3. 3DOM SiO$_2$-supported transition metal catalysts with various transition metal exhibit different catalytic activities. As shown in Figure S1B, the changing tendency of catalytic activities is very similar to the result of Table 3.

As shown in Table 3, the catalytic activities of 3DOM SiO$_2$-supported transition metal catalysts with varied transition metal oxides follow the order: MnO$_x$/SiO$_2$ > Co$_3$O$_4$/SiO$_2$ > Fe$_2$O$_3$/SiO$_2$ > CuO/SiO$_2$ > NiO/SiO$_2$. Combined the results of TEM (Figures 4) and H$_2$-TPR (Figures 8b-f), the different particle sizes, redox properties of transition metal oxides and valence state of transition metal element can explain the varied catalytic activities of 3DOM SiO$_2$-supported transition metal catalysts. The H$_2$-TPR results of as-prepared catalysts indicate that CuO/SiO$_2$ may give the highest catalytic activity for soot combustion due to the lowest reduction temperature among those catalysts. However, TEM image of CuO/SiO$_2$ exhibits that bulk CuO is formed, which is disadvantage for soot combustion owing to low contact effect between soot and catalyst. In addition, previous reports have proved that CuO does not have the capacity of adsorbing oxygen.$^{59,60}$ Therefore, CuO/SiO$_2$ catalyst presents very low
activity for particulate matter oxidation. TEM image of Fe₂O₃/SiO₂ displays that
Fe₂O₃ NPs with particle size of 4-13 nm are highly dispersed on the wall of 3DOM
SiO₂. This result suggests that soot and Fe₂O₃/SiO₂ catalyst may be well contacted
with soot. And 3DOM Fe₂O₃/SiO₂ catalyst is presumed to show high catalytic activity.
In fact, it exhibits lower catalytic activity than MnOₓ/SiO₂ and Co₃O₄/SiO₂ catalysts.
The reason for this phenomenon is that 3DOM Fe₂O₃/SiO₂ catalyst shows the highest
reduction temperature among those catalysts. Based on the above two reasons, 3DOM
Fe₂O₃/SiO₂ catalyst exhibits low catalytic activity for soot combustion. Except for
particle sizes and redox properties, the valence states also exhibit significant influence
on catalytic activity. As shown in the results of XPS, there are two kinds of valence
states for MnOₓ/SiO₂ while only one kind of valence state for other catalysts. The
catalyst with different valence states will enhance the capability of oxygen activation.
In the process of soot combustion, the redox reaction of Mn³⁺/Mn⁴⁺ in the MnOₓ/SiO₂
is in favor of forming oxygen vacancies on the surface of catalysts, and then the active
oxygen can be easily generated on the vacancies sites. Therefore, MnOₓ/SiO₂ shows
the highest catalytic activity for soot combustion.

In order to demonstrate the impaction of NO, we also tested the catalytic
performance of MnOₓ/SiO₂ under different reaction conditions, and the results are
listed in the following Table S2. Compared with pure soot, the MnOₓ/SiO₂ catalyst
shows super catalytic activity for soot combustion when they reacted under the same
reaction conditions (2000 ppm NO, 10% O₂). This result indicates that our prepared
catalysts exhibit high catalytic performance for soot combustion when NO is
participated in soot combustion. As shown in Table S2, the catalytic activities of MnOₓ/SiO₂ catalyst decrease with the decreasing of concentrations of NO. However, the catalytic activity of MnOₓ/SiO₂ is also much higher that pure soot even no NO is participated in the reaction. Those above results obviously demonstrate that the reaction pathways of soot combustion can be divided into two parts: One is that active oxygen species directly oxidize soot particles; the other one is that NO₂ acts as intermediate to catalyze soot oxidation.

The MnOₓ loading amount has a significant effect on the catalytic performance of 3DOM MnOₓ/SiO₂. The catalytic activity first increases with the increasing MnOₓ loadings (molar ratio of Mn to Si is 1:4), and then it decreases with further increasing of MnOₓ loading amount. The H₂-TPR results of 3DOM MnOₓ/SiO₂ with different MnOₓ loadings indicate that high MnOₓ loadings give large amount of H₂ consumption, which can increase the catalytic activity for soot combustion. However, there is a suitable MnOₓ loading amount for the catalyst to get high catalytic activity. Combined the TEM results in Figure 5, the particle sizes of MnOₓ NPs increase from 20 nm to 150 nm with increasing MnOₓ loadings (molar ratio of Mn to Si increased from 1:16 to 1:2). The free spread of soot particles in 3DOM structure would be blocked by big MnOₓ NPs (150 nm) owing to 90-140 nm of interconnected windows in 3DOM MnOₓ/SiO₂ (Figure 3). According to the above reasons, 3DOM MnOₓ/SiO₂ catalyst (molar ratio of Mn to Si is 1:4) exhibits the highest catalytic activity.

3.2.2 Stability of 3DOM MnOₓ/SiO₂ catalyst

In order to demonstrate the stability of as-prepared catalysts, the catalytic activity
and CO₂ selectivity of 3DOM MnOₓ/SiO₂ catalyst in five cycles were examined and the results are shown in Figure 10. The catalytic activity and CO₂ selectivity of 3DOM MnOₓ/SiO₂ catalyst keep constant after reaction for five times under the condition of loose contact between catalysts and soot particles. The temperature values of T₁₀, T₅₀ and T₉₀ are 297 ± 5, 355 ± 6 and 393 ± 5°C, respectively. Meanwhile, the CO₂ selectivity value is higher than 95% even after five-cycle reaction. The stability test results indicate that 3DOM MnOₓ/SiO₂ catalyst has good stability for soot combustion.

3.2.3 The effect of 3DOM structure in as-prepared catalysts on soot combustion

As a gas-solid-solid reaction, soot combustion is affected by two factors, including redox property of catalyst and contact efficiency between soot and catalyst. Besides the high redox property, the contact between soot and catalysts also plays an important role in improving the catalytic activity. Because loose contact between soot particles and catalysts is a main way of contact in the process of after-treatment for diesel engine exhaust, it is extremely important to study and design the active catalysts, which can improve the contact efficiency between the catalysts and soot particles under loose contact conditions. In this work, 3DOM SiO₂-supported transition metal catalysts with uniform macropores are designed and synthesized to enhance the contact efficiency. As shown in Figure 2 and Figure 4, the average diameter of ordered macroporous is about 310 nm and diameter of transition metal oxides NPs is lower than 50 nm (except for Co₃O₄/SiO₂ and CuO/SiO₂). Therefore,
soot particles could easily across those macropores and contact with transition metal oxides NPs (supported on the wall of 3DOM SiO$_2$). To demonstrate the macroporous effect, the soot and 3DOM MnO$_x$/SiO$_2$ catalyst was studied under the same conditions of TPO reaction to demonstrate the contact efficiency. In this confirmatory experiment, the reaction temperature of soot and 3DOM catalyst was programmed to 290 °C, which means the soot was not ignited. From the TEM image of Figure 11a, it can be seen that soot particles entered into the macropores of 3DOM MnO$_x$/SiO$_2$ catalyst. In addition, the outside soot particles could enter the inner pores of 3DOM catalyst with the help of the reaction gas flow (O$_2$, NO and Ar) during the reaction process owing to a gas-solid-solid reaction for soot combustion. More importantly, the rising reaction temperature may be contributed to accelerating the movement of soot particles. Under the influence of gas flow and rising temperature, the outside soot particles can easily enter into the 3DOM structure and contact the inner active sites of 3DOM catalyst. As shown in the Figure 11b, the macropores of 3DOM MnO$_x$/SiO$_2$ are well contacted with soot particles, indicating that 3DOM structure is a desirable feature for diesel soot combustion. As shown in the HRTEM images (Figure 11c), the soot and MnO$_x$ NPs are well contact with each other in the inner of 3DOM structure. Therefore, the number of available active sites of catalysts can be maximized through macroporous effect, especially for inner active sites of catalysts. More active sites would result in higher catalytic activity. TEM results directly demonstrate that soot particles can easily enter the interior of 3DOM catalysts with the help of the airflow in the reaction process under the loose contact conditions, and have less resistance to go through the
catalyst structure. In fact, our group has synthesized a series of 3DOM materials and they show higher catalytic activities than the corresponding particle materials. Therefore, it is significantly important to study and design 3DOM structure for soot combustion.

4. Conclusions

In summary, 3DOM SiO$_2$ support was successfully synthesized by CCT method. Different transition metal oxides NPs with varied sizes are supported on the skeleton of 3DOM SiO$_2$ by simple incipient-wetness impregnation method. All 3DOM SiO$_2$-supported transition metal catalysts show high periodical arrayed macropores and interconnected small windows. 3DOM SiO$_2$-supported catalysts with different transition metal oxides NPs exhibit different catalytic activities for soot combustion. Compared with pure soot, 3DOM MnO$_x$/SiO$_2$ catalyst with molar ratio of Mn:Si is 1:4 shows the highest catalytic activity among the as-prepared catalysts, which $T_{10}$, $T_{50}$ and $T_{90}$ are 297, 355 and 393 $^\circ$C, respectively. The CO$_2$ selectivity of as-prepared catalysts is also higher than 93%. The macroporous effects of 3DOM structure, redox properties of transition metal oxides and sizes of transition metal oxide NPs significantly affect the catalytic activity for soot combustion simultaneously. The as-prepared catalysts are promising for practical applications in the catalytic oxidation of diesel soot particles owing to high activity and low cost.
