This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. This Accepted Manuscript will be replaced by the edited, formatted and paginated article as soon as this is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
Unsymmetrically Functionalized Benzoporphyrins

R. G. Waruna Jinadasa, a Yuanyuan Fang, b Yongming Deng, a Rohit Deshpande, a Xiaqin Jiang, b Karl M. Kadish, b* and Hong Wang b*

The synthesis of unsymmetrical push-pull benzoporphyrins has been realized. UV-Vis and fluorescence spectroscopy, cyclic voltammetry and DFT calculations reveal subtle substituent effects on the electronic and optical properties of these porphyrins.

π-Extended porphyrins in which one or more aromatic rings are fused to the porphyrin periphery at the β, β'-positions have attracted considerable attention owing to their unique combination of photophysical, optoelectronic, and physicochemical properties, and their potential applications in various areas such as organic electronics, optic electronic and photomedicines. 1 Although known for decades, the investigation of π-extended porphyrins has been mainly restricted to symmetrical structures. Reports of unsymmetrical π-extended porphyrins are rare due to the limited synthetic methods to access these compounds. 2 In particular π-extended porphyrins with unsymmetrically substituted functional groups remain elusive in the literature. Unsymmetrically substituted porphyrins are expected to display different electronic and photophysical properties from their symmetrical counterparts due to a splitting of the frontier orbitals, and may hold promise for future broader applications. Herein, we report the synthesis of a series of unsymmetrically functionalized benzoporphyrins in which a push (electron-donating) group and a pull (electron-withdrawing) group are installed at the porphyrin β-positions, and characterized by UV-Vis and fluorescence spectroscopy, and cyclic voltammetry. DFT calculations of these porphyrins were performed to provide insights into their electronic and optical properties. Design and synthesis of the unsymmetrically functionalized porphyrins (Scheme 1, 3-5) takes advantage of a concise and versatile method developed in our laboratory for the synthesis of benzoporphyrins, 3 and the unique reactivity of 2-nitro-tetraarylporphyrins. 4 In this method, an alkene reacts with a β, β'-dibromoporphyrin through a three-step cascade reaction involving a vicinal two-fold Heck reaction, 6-π electrocycloaddition, and subsequent aromatization to afford the benzoporphyrin. We wished to design and synthesize unsymmetrical push-pull benzoporphyrins in which both an electron-withdrawing group and an electron-donating group were incorporated at the porphyrin periphery. The presence of a nitro group at the porphyrin β-position can serve as an anchor and direct the bromination of the free base porphyrin to the β, β'-positions at the opposite pyrrole ring to afford the dibromoporphyrin 1 . 4 After metal insertion of free base porphyrin 1 , the resulting Zn(II) dibromoporphyrin 2 was reacted with substituted alkynes through the Heck-based cascade reaction leading to the benzoporphyrin 3 . The nitro group is a strong electron-withdrawing group. As such, we used styrene and 4-methoxystyrene in this reaction to introduce an electron-donating group at the opposite position of the porphyrin ring to afford the push-pull unsymmetrical porphyrins 3a and 3b. On the other hand, we used methyl acrylate to introduce two vicinal ester groups to the fused benzene ring, serving as moderate electron-withdrawing groups to give the unsymmetrical pull-pull benzoporphyrin 3c. The nitro group was then reduced to an amine using NaBH₄ to give aminoporphyrin A. Aminoporphyrin A was not stable, and was further converted into an amide through acylation to generate another type of push-pull benzoporphyrin (4 and 5). 5 The carbonylamino group serves as “push” functionality. For comparison purposes, the symmetrical benzoporphyrin 6 was also prepared through denitration of 3. 4 UV-Vis and fluorescence spectra of these porphyrins are compiled in Fig. 1 and Fig S1 (see Supporting Information). As compared with the symmetrical benzoporphyrin 6, the unsymmetrical benzoporphyrins 3-5 all display broadened and red shifted Soret and enhanced Q bands corresponding to the symmetry breaking of the structure. The unsymmetrical

pull-pull nitroporphyrin 3c exhibits a Soret band at 446 nm. Upon switching from a moderately electron-withdrawing ester group to an electron-donating phenyl group (3a), the Soret band is red shifted to 449 nm, while the Q bands remain mostly unchanged; installing a strong electron-donating methoxy group at the 4-position of the phenyl ring (3b) pushes the Soret band slightly further to the red region (452 nm). These data demonstrate the expected "push-pull" effect. Interestingly, the push-pull benzoporphyrins 4 and 5 show blue shifted absorption bands relative to those of pull-pull 3c. While the symmetrical benzoporphyrin 6 displays a strong fluorescence band at 664 nm with a weaker shoulder at 607 nm, the emission bands for the unsymmetrical porphyrins 4 and 5 are red shifted to 713/714 nm (main band) and 654/655 nm (shoulder), once again demonstrating the lack of symmetry and push-pull effects. On the other hand, porphyrins 3a-3c exhibit similar emission bands regardless of the types of substituents at the porphyrin periphery (Fig. S1). These emission bands are much broader and red-shifted (740-743 nm), and are also much attenuated relative to those of 4-6. This fluorescence quenching effect is likely related to the electronic perturbation of the directly conjugated nitro group to the porphyrin, which is a strong fluorescence quencher of fluorescent dyes. Upon demetallation of 3a-3c, their emission bands split and become more intense relative to those of 3a-3c (Fig. 1 and Fig. S2 and S3); treatment of these free base porphyrins with trifluoroacetic acid (TFA) results in almost complete quenching of the fluorescence; in sharp contrast, when the demetallated 3a-3c is treated with triethylamine (TEA), the emission bands are significantly enhanced instead. These interesting phenomena were not observed for free base porphyrin of 6 that does not contain a nitro group. The free base porphyrin of 6 exhibits expected enhanced fluorescence upon treatment of TFA, and remains unchanged in the presence of TEA (Fig S4).

The electrochemical properties of these mono-benzoporphyrins were investigated using cyclic voltammetry (CV) (Fig. 2 and Table S1 in SI). The reductions were measured in pyridine and the oxidations in CH$_2$Cl$_2$ in order to obtain thermodynamically reversible electrode reactions for all processes. For comparison purposes, the CV of ZnTPP was also measured under similar conditions. Several trends were observed in the electrochemical data. Porphyrin 6 displays two reversible oxidations and two reversible reductions, similar to (TPP)Zn. As compared with (TPP)Zn, both the first ($E_{1/2} = 0.75$ V) and second oxidation ($E_{1/2} = 0.97$ V) potentials of 6 are shifted negatively, while both the first ($E_{1/2} = -1.34$ V) and second ($E_{1/2} = -1.78$ V) reductions move in a positive direction. These shifts in redox potentials are anticipated for porphyrin 6 due to its extended π-conjugation upon fusion of a benzene ring to the porphyrin periphery. The reduced HOMO-LUMO gap of 6 is also reflected by its red-shifted and broadened absorption bands relative to those of (TPP)Zn. Two reversible oxidations and two reversible reductions were also observed for porphyrin 3a-3c. The introduction of a strong electron-withdrawing nitro group influenced the reduction potentials more significantly than the oxidation potentials. While the oxidation potentials of 3a-3b only shifted positively by 30-90 mV relative to those of 6, the reduction potentials shifted by 260-480 mV. The push-pull porphyrins 3a and 3b display exactly the same the first oxidation and the first reduction potentials; the second oxidation and the second reduction potentials of 3a and 3b only deviate slightly from each other, and are negatively shifted by 20 mV and 10 mV, respectively in 3b. These data suggest that the presence of a strong electron-donating group (-OMe) at the para-position of the phenyl ring in 3b does not significantly influence the electrochemical properties of the porphyrin. This is likely due to the hindered electronic communication between the electron-donating methoxy group with the porphyrin ring. As shown in the calculated optimized geometry (Fig. S6), the aryl groups on the fused benzene rings of 3a and 3b preferably adopt a perpendicular position to the porphyrin plane; as a result, the π-conjugation of the porphyrin does not effectively extend to the attached aryl rings on the fused benzene unit. On the other hand, when the weakly electron-donating aryl groups in 3a and 3b are replaced with moderately electron-withdrawing ester groups of 3c, oxidation and reduction potentials are positively shifted by 50 to 140 mV, showing a more pronounced substituent effect. Converting the strongly electron-withdrawing nitro group in 3c into a moderately electron-donating carbonylamino group in porphyrins 4 and 5 significantly shifts the reduction potentials negatively by 300 to 460 mV. The oxidation potentials of 4 and
5 also shift moderately in a negative direction. It is notable that an extra reversible oxidation (third oxidation) was observed for 4 at $E_{1/2} = 1.38$ V, which likely results from oxidation of the carbonylamino group.

DFT calculations were performed to provide some insights into the electronic and electrochemical properties of the porphyrins (Fig S5 in SI). The frontier orbitals of these porphyrins display different electron density patterns. While both the HOMO and the LUMO of 6 mainly involve the porphyrin core, the electron density in the HOMO of 4 and 5 is extended to the fused benzene ring and the carbonylamino group. The HOMOs of 4 and 5 are destabilized and the LUMOs of 4 and 5 are stabilized as a result of the introduction of the moderately electron-donating carbonylamino group, leading to a smaller HOMO-LUMO energy gap relative to that of 6. The electron density of the HOMOs for push-pull porphyrins 3a and 3b is mainly located on the porphyrin core with partial extension to the fused benzene ring. The involvement of the fused benzene ring in the HOMO of 3b is slightly larger than that of 3a due to the electron-donating methoxy group presence at the para-position of the attached phenyl ring. The electron density on the HOMO of pull-pull 3c is distributed from the fused benzene ring through the porphyrin core to the nitro group. On the other hand, the LUMO of 3a-3c shows a reversed trend in the electron density distribution. Both the HOMOs and LUMOs of 3a-3c are stabilized relative to that of 6. For the HOMO, the stabilization order is 3b $>$ 3a $>$ 3c; for the LUMO, the stabilization order is 3c $>$ 3a $>$ 3b. The HOMO-LUMO energy gap follows the order: 3b $<$ 3a $<$ 3c $<$ 6, correlating well with their electronic and electrochemical properties. It is notable that the orbital splitting in the LUMOs of pull-pull 3a-3c are more significant than that of 4 and 5.

In summary, unsymmetrically functionalized benzo[6,15]porphyrins, in which both an electron-withdrawing group and an electron-donating group are located at the porphyrin $\beta$-positions, were synthesized. Breaking the symmetry of the benzo[6,15]porphyrin results in a significant broadening and red shifting of the absorption and emission bands. The introduction of different types of substituents to the porphyrin periphery makes remarkable difference in the electrochemical and electronic properties of these porphyrins. The strongly electron withdrawing nitro group appears to have a more pronounced impact on the properties of the benzo[6,15]porphyrins than the electron-donating aminocarbonyl and aryl groups. Fluorescence quenching was observed for 3a-3c and for their free base porphyrins, which display unusual fluorescence behaviour upon treatment with an acid or a base. These interesting results are apparently related to electronic perturbations of the nitro group on the porphyrin $\pi$-system, and are worthy of further investigation. This work provides useful information that is lacking in the field, and may open the door to functionalizing new benzo[6,15]porphyrins for various applications.
