This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. This *Accepted Manuscript* will be replaced by the edited, formatted and paginated article as soon as this is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

27 **Abstract**

28 To investigate the effect of organic ligands on the coordination frameworks, seven
29 new nickel complexes with formulae $\text{Ni}(\text{BDC})(\text{titmb})\cdot 3\text{H}_2\text{O}$ (**1**),
30 $\text{Ni}_2(\text{BDC})_2(\text{bimb})_2(\text{H}_2\text{O})_2\cdot 3\text{H}_2\text{O}$ (**2**), $\text{NiZn}(\text{BTC})(\text{titmb})\text{Br}$ (**3**), $\text{Ni}(\text{TBDC})(\text{titmb})(\text{H}_2\text{O})$
31 (**4**), $\text{Ni}(\text{TBDC})(\text{bix})\cdot \text{H}_2\text{O}$ (**5**), $\text{Ni}(\text{TBDC})(\text{mbix})(\text{H}_2\text{O})\cdot \text{H}_2\text{O}$ (**6**) and
32 $\text{Ni}(\text{TBDC})(\text{obix})(\text{H}_2\text{O})$ (**7**) (titmb = 1,3,5-tris(1-imidazol-1-ylmethyl)-2,4,6-tri-
33 methylbenzene, bimb = 4,4'-bis(imidazol-1-ylmethyl)biphenyl, bix =
34 1,4-bis(imidazol-1-ylmethyl)benzene, mbix = 1,3-bis(imidazol-1-ylmethyl)benzene,
35 obix = 1,2-bis(imidazol-1-ylmethyl)benzene, H_3BTC = 1,3,5-benzenetricarboxylic
36 acid, H_2BDC = isophthalic acid, H_2TBDC = 5-(tertbutyl)isophthalic acid), have been
37 synthesized and characterized by elemental analyses, infrared spectra (IR),
38 thermogravimetric analyses (TGA) and single-crystal X-ray diffraction. Single crystal
39 structure analysis shows that complex **1** shows a three-dimensional (3D)
40 (3,5)-connected network with the topology of $(6^3)(6^9.8)$. Complexes **2** and **6** have
41 similar two-dimensional (2D) lamella structure with (4,4) topology. Complex **3**
42 exhibits an interesting 3D (3,6)-connected framework by self-penetration of two sets
43 of (10,3)-a nets. Complex **4** presents a unusual 2D (3,5)-connected framework with
44 the topology of $(3.5^2)(3^2.5^3.6^4.7)$. Complex **5** features a 3D two-fold interpenetrating
45 framework with $(4^6.6^4)$ -**bnn** hexagonal BN topology, whereas Complex **7** possesses
46 an interesting one-dimensional (1D) independent single-wall metal-organic nanotube.
47 The various dimensions and structural features of seven complexes may be attributed
48 to the different species of functional groups, the number and position of the
49 carboxylic groups in the carboxylates as well as the auxiliary ligands play a

50 significant role in promoting the diversity of the observed structural motifs. The SHG
51 properties of **1**, **3** and **4** as well as ferroelectric properties for **1** have also been
52 investigated.

55 ligands; nonlinear optical property; ferroelectric property

56

57 **Introduction**

58 Rational design and synthesis of coordination polymers (CPs) with tailor-made
59 structures have been one of the most attractive areas in crystal engineering and
60 supramolecular chemistry, because coordination polymers with desired structures
61 possess interesting functionalities and can act as potential materials in the field of gas
62 storage and separation, magnetism, catalysis, non-linear optics, luminescence and ion
63 exchange.¹⁻⁶ In the realm of CPs, structure control is fundamental for determining the
64 properties and applications of the crystalline materials. Accordingly, numerous
65 intriguing structures and associated interesting properties have been investigated in
66 depth.⁷⁻⁸ Though great progress and developments have been made in the construction
67 of diverse architectures, the prediction of the precise solid-state structures or the
68 control of structural dimensionality of CPs remains a long-term challenge in the field
69 of crystal engineering.⁹ Many factors affect the structural assembly process of the CPs,
70 such as the metal, the ligand, temperature, pH value of the reaction, the solvent, the
71 counter anions, and the ratio of ligand and metal.¹⁰⁻¹⁵ It has been established that the

72 ligands are crucial for the structural architectures and functionalities of CPs as the
73 structures and properties of these complexes are usually influenced by the flexibility,
74 shape, symmetry, length and substituent groups of ligands.¹⁶

75 Polycarboxylates are often used as bridging ligands to prepare CPs due to their
76 versatile coordination modes, high structural stability and the ability to balance the
77 positive charges.¹⁷ Moreover, in view of the previous reports, it is found that angular
78 dicarboxylates (isophthalic acid) and its derivatives (5-nitroisophthalic acid) may have
79 an influence on the assembling processes, the structures and even the properties of
80 CPs due to their geometric and electronic effects, while the use of the large hindrance
81 of the derivatives of the dicarboxylate remains largely unexplored. To the best of our
82 knowledge, there have been only a few reported coordination polymers based on the
83 H₂TBDC ligand.¹⁸ As is well known, the mixed ligand strategy added the scope of the
84 CPs, giving diversified polymeric structures with interesting structures and unusual
85 properties.¹⁹ In this regard, bridging imidazole ligands have chance to find their niche
86 in the crystal engineering. Up to now, the bis(imidazole) ligands have been justified as
87 an efficient and versatile organic building unit for construction of coordination
88 polymers by Cui and Zheng et al. groups;²⁰ however, we believe that the CPs of these
89 ligands with varied structures and topologies could still be achieved by changing
90 assembly environments and strategies. As continuous exploration on the study of
91 Ni(II)-CPs with angular dicarboxylate and different imidazole-containing ligands,
92 seven nickel coordination polymers, namely, Ni(BDC)(titmb)·3H₂O (**1**),
93 Ni₂(BDC)₂(bimb)₂(H₂O)₂·3H₂O (**2**), NiZn(BTC)(titmb)Br (**3**), Ni(TBDC)(titmb)(H₂O)

94 (4), Ni(TBDC)(bix)·H₂O (5), Ni(TBDC)(mbix)(H₂O)·H₂O (6) and
95 Ni(TBDC)(obix)(H₂O) (7), have been successfully obtained. They are characterized
96 by elemental analysis and X-ray crystallography. The crystal structures as well as
97 topological analysis of these complexes will be represented and discussed in detail. In
98 addition, their physical properties are also studied.

99 **Experimental section**

100 **Materials and general methods**

101 All the reagents and solvents for syntheses and analyses were purchased from Sigma
102 or TCI and employed as received without further purification. The titmb, bimb, bix,
103 mbix and obix ligands were prepared according to the reported method.²¹ Elemental
104 analyses (C, H and N) were performed on a Vario EL III elemental analyzer. Infrared
105 spectra were performed on a Nicolet AVATAR-360 spectrophotometer with KBr
106 pellets in the 4000 - 400 cm⁻¹ region. Thermal gravimetric analyses (TGA) were
107 performed on a Netzsch STA-409PC instrument in flowing N₂ with a heating rate of
108 10 °C min⁻¹. The second-order nonlinear optical intensity was estimated by measuring
109 a powder sample relative to urea. A pulsed Q-switched Nd:YAG laser at a wavelength
110 of 1064 nm was used to generate a SHG signal from powder samples. The
111 backscattered SHG light was collected by a spherical concave mirror and passed
112 through a filter that transmits only 532 nm radiation. The ferroelectric property of the
113 solid-state sample was measured by the Premier II ferroelectric tester at room
114 temperature.

115 **Preparation of Ni(BDC)(titmb)·3H₂O (1).** A mixture containing Ni(NO₃)₂·6H₂O

116 (58.2 mg, 0.2 mmol), H₂BDC (19.3 mg, 0.1 mmol), titmb (36.0 mg, 0.1 mmol) and
117 LiOH·H₂O (8.4 mg, 0.2 mmol) in 15 ml deionized water was sealed in a 25 mL Teflon
118 lined stainless steel container and heated at 140 °C for 3 days. Green block crystals of
119 **1** were collected by filtration and washed with water and ethanol several times with a
120 yield of 71%. Anal. calcd for C₂₉H₃₄N₆O₇Ni: C 54.65; H 5.38; N 13.19; Found: C
121 54.66; H 4.36; N 13.17%. IR(KBr pellet, cm⁻¹): 3459 (br), 3057 (w), 2923 (w), 1607
122 (s), 1541 (s), 1520 (m), 1444 (w), 1432 (m), 1382 (s), 1282 (w), 1233 (m), 1130 (w),
123 1109 (m), 1087 (m), 1033 (m), 947 (w), 853 (w), 821 (m), 767 (w), 679 (w), 532 (w).

124 **Preparation of Ni₂(BDC)₂(bimb)₂(H₂O)₂·3H₂O (2).** A mixture containing
125 Ni(NO₃)₂·6H₂O (58.2 mg, 0.2 mmol), H₂BDC (19.3 mg, 0.1 mmol), bimb (39.2 mg,
126 0.1 mmol) and NaOH (8.0 mg, 0.2 mmol) in 15ml deionized water was sealed in a 25
127 mL Teflon lined stainless steel container and heated at 160 °C for 3 days. Green block
128 crystals of **2** were collected by filtration and washed with water and ethanol several
129 times with a yield of 57% based on H₂BDC. Anal. calcd for C₅₆H₅₄N₈O₁₃Ni₂: C 57.76;
130 H 4.67; N 9.62; Found: C 57.74; H 4.68; N 9.61%. IR(KBr pellet, cm⁻¹): 3471 (br),
131 3057 (w), 2827 (w), 1603 (s), 1585 (s), 1522 (m), 1442 (m), 1383 (s), 1288 (w),
132 1203(w), 1091 (m), 933 (w), 837 (m), 753 (m), 631 (w), 562 (w).

133 **Preparation of NiZn(BTC)(titmb)Br (3).** A mixture containing Ni(NO₃)₂·6H₂O
134 (29.1 mg, 0.1 mmol), ZnBr₂ (22.5 mg, 0.1 mmol), H₃BTC (21.0 mg, 0.1 mmol), titmb
135 (36.0 mg, 0.1 mmol) and NaOH (12.0 mg, 0.3 mmol) in 15 ml deionized water was
136 sealed in a 25 ml Teflon lined stainless steel container and heated at 180 °C for 3 days.
137 Pale green cubic crystals of **3** were collected by filtration and washed with water and

138 ethanol several times with a yield of 42%. Anal. calcd for $C_{30}H_{27}BrN_6O_6NiZn$: C
139 46.70; H 3.53; N 10.89; Found: C 46.72; H 3.56; N 10.88%. IR(KBr pellet, cm^{-1}):
140 3452 (br), 3092 (w), 2823 (w), 1610 (s), 1578 (s), 1520 (s), 1446 (m), 1387 (m), 1293
141 (m), 1250 (m), 1111 (m), 1091 (m), 1013 (m), 945 (m), 867 (w), 810 (w), 773 (m),
142 759 (m), 674 (w), 587 (m).

143 **Preparation of Ni(TBDC)(titmb)(H₂O) (4).**

144 Ni(NO₃)₂·6H₂O (29.1 mg, 0.1 mmol), H₂TBDC (22.2 mg, 0.1 mmol), timb (36.0 mg,
145 0.1 mmol), NaOH (8 mg, 0.2 mmol) and 15 mL deionized water in a 25 mL Teflon
146 lined stainless steel container at 160 °C for 4 days produced green block crystals of **4**
147 in 69% yield after washing with water and ethanol several times. Anal. Calcd for
148 C₃₃H₃₅N₆O₅Ni: C 60.29; H 5.83; N 12.78; Found: C 60.28; H 5.81; N 12.77%.
149 IR(KBr pellet, cm^{-1}): 3449 (br), 3062 (m), 1609 (s), 1571 (s), 1519 (m), 1383 (s),
150 1231 (w), 1093 (m), 875 (m), 822 (m), 765 (m), 716 (m), 653 (m), 569 (w), 462(w).

151 **Preparation of Ni(TBDC)(bix)·H₂O (5).**

152 A mixture containing Ni(NO₃)₂·6H₂O (29.1 mg, 0.1mmol), H₂TBDC (22.2 mg, 0.1
153 mmol), bix (23.6 mg, 0.1 mmol) and LiOH·H₂O (8.4 mg, 0.2 mmol) in 15 mL
154 deionized water was sealed in a 25ml Teflon lined stainless steel container and heated
155 at 170 °C for 3 days. Green block crystals of **5** were collected by filtration and washed
156 with water and ethanol several times with a yield of 48%. Anal. Calcd for
157 C₃₃H₃₅N₆O₅Ni: C 60.57; H 5.39; N 12.84; Found: C 60.55; H 5.41; N 12.85%.
158 IR(KBr pellet, cm^{-1}): 3453 (s), 3098 (w), 2823 (w), 1609 (s), 1589 (s), 1520 (m), 1442
159 (m), 1401 (s), 1375 (s), 1298 (w), 1126 (w), 1091 (m), 922 (m), 839 (s), 765 (m), 673

160 (w), 521(m).

161 **Preparation of Ni(TBDC)(mbix)(H₂O)·H₂O (6).**

162 The preparation of **6** was similar to that of **5** except that mbix was used instead of bix
163 as auxiliary ligand. Green pillar crystals of **6** were collected in a 57% yield. Anal.
164 Calcd for C₂₆H₃₀N₄O₆Ni: C 56.45; H 5.47; N 10.13; Found: C 56.47; H 5.48; N
165 10.15%. IR(KBr pellet, cm⁻¹): 3466 (m), 3159 (w), 3059 (w), 2829 (w), 1586 (s),
166 1522 (m), 1447 (m), 1393 (s), 1298 (w), 1103 (m), 1089 (m), 951 (m), 922 (m), 835
167 (w), 795 (w), 744 (m), 711 (m), 659 (m), 544 (w).

168 **Preparation of Ni(TBDC)(obix)(H₂O) (7).**

169 Complex **7** was prepared in the same way as that for **5** but using obix instead of bix as
170 auxiliary ligand. Green block crystals of **7** were collected in a 61% yield. Anal. Calcd
171 for C₂₆H₂₈N₄O₅Ni: C 58.35; H 5.27; N 10.47; Found: C 58.33; H 5.29; N 10.44%.
172 IR(KBr pellet, cm⁻¹): 3457 (m), 3189 (m), 2826 (w), 1605 (s), 1582 (s), 1520 (m),
173 1441 (m), 1378 (s), 1256(m), 1179 (m), 1091 (s), 955 (w), 874 (w), 833 (s), 792 (m),
174 745 (s), 663 (m), 555 (w).

175 **X-Ray crystallography**

176 Crystallographic data collections for complexes **1** - **7** were carried out on a Bruker
177 Smart Apex II CCD with graphite-monochromated Mo-K α radiation ($\lambda = 0.71073$ Å)
178 at 293(2) K using the ω -scan technique. The data were integrated by using the SAINT
179 program,²² which was also used for the intensity corrections for the Lorentz and
180 polarization effects. An empirical absorption correction was applied using the
181 SADABS program.²³ The structures were solved by direct methods using the program

182 SHELXS-97 and all non-hydrogen atoms were refined anisotropically on F^2 by the
183 full-matrix least-squares technique using the SHELXL-97 crystallographic software
184 package. The hydrogen atoms of the organic ligands were refined as rigid groups.
185 Some of the water hydrogen atoms in complex **2** could not be positioned reliably.
186 Other hydrogen atoms of water molecules were located from difference Fourier maps.
187 All calculations were performed on a personal computer with the SHELXL-97
188 crystallographic software package.²⁴ The details of the crystal parameters, data
189 collection and refinement for the complexes are summarized in Table 1, and selected
190 bond lengths and angles with their estimated standard deviations are listed in Table S1.
191 CCDC-804097 (**1**), 733836 (**2**), 936716 (**3**), 936717 (**4**), 936718 (**5**), 936719 (**6**) and
192 936720 (**7**) contain the crystallographic data for this paper.

193

194

<Table 1 here>

195

196 **Results and discussion**

197 **IR spectra**

198 For complexes **1** - **7**, the observed bands of 3400 – 3400 cm^{-1} characterize water
199 molecules in the structures, while the bands of C - H of aromatic rings at 2830 – 2820
200 cm^{-1} . The IR spectra show the absence of the characteristic bands at around 1700 cm^{-1}
201 attributed to the protonated carboxylate group indicates that the complete
202 deprotonation of the polycarboxylic acids upon reaction with metal ion. The
203 characteristic bands of carboxyl groups are shown in the range of 1540 - 1620 cm^{-1} for

204 antisymmetric stretching and 1360 - 1460 cm^{-1} for symmetric stretching. The
205 separations (Δ) between $\nu_{\text{asym}}(\text{CO}_2)$ and $\nu_{\text{sym}}(\text{CO}_2)$ bands indicate the presence of
206 different coordination modes. The IR spectra exhibit the characteristic peaks of
207 imidazole groups at *ca.*1520 cm^{-1} . The bands in the region 640 -1310 cm^{-1} are
208 attributed to the -CH- in-plane or out-of-plane bend, ring breathing, and ring
209 deformation absorptions of benzene ring, respectively. The bands in the region 640 -
210 1250 cm^{-1} are attributed to the -CH- in-plane or out-of-plane bend, ring breathing, and
211 ring deformation absorptions of benzene ring, respectively.²⁵

212

213 **Crystal structure of Ni(BDC)(titmb)·3H₂O (1)**

214 Complex **1** crystallizes in the orthorhombic acentric space group *Pna*2₁, the
215 asymmetric unit contains one Ni(II) ion, one BDC²⁻ anion, one titmb ligand and three
216 lattice water molecule. The Ni(II) ion is six-coordinated and close to an octahedron
217 NiN₃O₃ geometry. As illustrated in Fig. 1a, three oxygen atoms (O1, O2 and O4A)
218 belonging to two different BDC²⁻ anions and one titmb nitrogen atom (N3B) are
219 ligated to the Ni(II) ion in the equatorial plane, with the other two nitrogen atoms
220 (N1C and N5) arising from the titmb ligand situated in the axial position. Each Ni(II)
221 approximately lies in the equatorial position with a maximum deviation (0.024 Å)
222 from the basal plane. In the structure, Ni-O and Ni-N bond distances are in the range
223 of 2.004(3)–2.200(3) and 2.043(4)–2.069(4) Å, respectively. Each titmb ligand in turn
224 connects three Ni(II) ions which form a triangle with edge lengths (Ni···Ni) of 9.367,
225 11.862 and 12.954 Å, respectively. The three imidazolyl rings are inclined to the

226 phenyl ring with angles of 85.98°, 86.25° and 82.17°, respectively. As shown in Fig.
227 1b, each Ni(II) ion connects three titmb ligands and each titmb ligand connects three
228 Ni(II) ions, such a coordination mode makes the complex a 2D network with
229 honeycomb structure, and a schematic drawing is shown in Fig. 1c. It is obvious that
230 all titmb ligands in the network have *cis*, *trans*, *trans*-conformation with up- and
231 down-orientations alternatively. BDC²⁻ anions adopt monodentate and bidentate
232 chelate coordination modes and connect the Ni-titmb layers as pillars to generate a 3D
233 structure (Fig. 1d). If the Ni(II) ion is considered as a five-connected node (connecting
234 to two BDC²⁻ anions and three titmb ligands), the titmb ligand can be considered as a
235 three-connected node (connecting to three Ni(II) ions), and the structure of **1** can be
236 classified as a rare binodal (3,5)-connected (6³)(6⁹.8) topology (Fig. 1e). In addition,
237 the 3D structure of **1** is further stabilized by intermolecular H-bonding interactions.

238

239 <Figure 1 here>

240

241 **Crystal structure of Ni₂(BDC)₂(bimb)₂(H₂O)₂·3H₂O (**2**)**

242 Employing the bridging bimb ligand in this system, the reaction yielded complex **2**
243 showing a much different structure from **1**. Fig. 2a illustrates the coordination
244 environments of the Ni(II) ions. The crystallographically independent Ni(II) ion is
245 six-coordinated by two nitrogen atoms from two different bimb ligands, three
246 carboxylate oxygen atoms from two BDC ligands and one coordinated water molecule
247 to construct a distorted octahedral geometry. The Ni–O bond lengths are in the range

248 of 2.0273(17)–2.1369(17) Å, the Ni–N bond lengths are 2.063(2) and 2.071(2) Å and
249 the coordination angles around Ni(II) ion are in the range of 61.61(7)°–178.79(8)°.
250 The two carboxylate groups of the BDC ligands adopting monodentate and bidentate
251 chelate coordination modes link two Ni(II) atoms to form a one-dimensional chain
252 with Ni···Ni distances of 10.11 Å. These chains are further extended by bimb ligands
253 into a 2D framework. It is interesting that the Ni(II) atoms all lie in the same plane,
254 parallel to the *ab* plane, and are joined through two types of ligands, above the plane
255 by one kind, and below by the other kind. The connection with the BDC²⁻ anions
256 occurs along the *a* direction, while with the bimb ligands the joining is made along the
257 *c* direction. So, the 2D structure formed is the 4-connected (4,4)-**sql** net (Fig. 2b). The
258 undulated layers stack in an interweaving way along the *b* direction, to generate a 3D
259 structure with open channels (Fig. 2c). After the removal of these free water
260 molecules, PLATON²⁶ calculations show that the volume of the effective void is 5.5%
261 of the unit-cell volumes. In addition, intramolecular O1W–H1WA···O3 (2.699(3) Å),
262 O1W–H1WB···O2W (2.752(4) Å), O2W–H2WA···O3 (2.683(4) Å) and O2W–
263 H2WB···O3W (2.680(6) Å) hydrogen-bonding interactions exist among the lattice
264 water molecules and carboxylate oxygen atoms, which further stabilized the 2D
265 structure of **2** (Fig. 2d).

266

267

<Figure 2 here>

268

269 **Crystal structure of NiZn(BTC)(titmb)Br (3)**

270 X-ray single crystal diffraction analysis reveals that the asymmetric unit of **3** consists
271 of one nickel ion and one unique zinc ion (the Ni : Zn ratio of 1 : 1 based on ICP
272 analysis) bridged by three carboxylate groups, one crystallographically independent
273 titmb ligand, one individual BTC^{3-} anion and one coordinated bromide ion. As shown
274 in Fig. 3a, each Zn(II) ion is tetrahedral coordinated by three oxygen atoms (O2, O2A
275 and O2B) from three different BTC^{3-} anions and one terminal bromide ion (Br1).
276 Each Ni(II) ion is surrounded by three nitrogen atoms (N1, N1C and N1D) from three
277 distinct titmb ligands and three oxygen atoms (O1, O1C and O1D) from three
278 different BTC^{3-} anions to furnish a distorted octahedral geometry. One Zn(II) ion and
279 one Ni(II) ion are connected by three carboxylate groups in a bidentate-bridging
280 fashion to form a binuclear $\text{ZnNi}(\text{CO}_2)_3\text{Br}$ unit, as exhibited in Fig. 3b. Each BTC^{3-}
281 anion connect with three Zn ions and three Ni ions from three different binuclear units
282 and each titmb ligand bridges three Ni ions from three individual binuclear units, thus
283 each binuclear unit is linked by six organic ligands (three titmb ligands and three
284 BTC^{3-} anions) to generate a (3,6)-connected network. The overall 3D network is so
285 intricate that it is described in terms of two subnets. For the first subnet, the titmb
286 ligands are omitted, the binuclear units can be considered 3-connected nodes. Each
287 binuclear unit is bridged to three different BTC^{3-} anions. Thus the whole subnet
288 structure can be extended to a slightly distorted (10,3)-a net with left-handedness of
289 helices in the direction of *c* axis as shown in Fig. 3c. The extended Schläfli symbol of
290 this net is $10_5.10_5.10_5$. From another point of view, the BTC^{3-} anions are ignored for
291 the second subnet. Interestingly, a heavily distorted (10,3)-a net with right-handedness

292 of helices is obtained as displayed in Fig. 3d. It is obvious that all titmb ligands in the
293 network have *cis, cis, cis*-conformation.

294 To describe the overall topology of complex **3**, we add the titmb ligand to the
295 first subnet or add the BTC³⁻ ligand to the second subnet. Thus we get an
296 unprecedented (6³)₂(6¹².8³) net calculated by the TOPOS program²⁷ (Fig. 3e). To the
297 best of our knowledge, the network represents a novel (3,6)-connected topology
298 which is different from the rutile and rutile-related topology²⁸ by self-penetration of
299 two sets of (10,3)-a nets.

300

301 <Figure 3 here>

302

303 **Crystal structure of Ni(TBDC)(titmb)(H₂O) (**4**)**

304 The polymeric structure of **4** was confirmed by X-ray single crystal structure analysis.

305 The complex crystallizes in the orthorhombic space group *P2₁2₁2₁* and Fig. 4a shows

306 the asymmetric unit of **4** with atom numbering scheme. Each Ni(II) atom is

307 coordinated by three imidazole nitrogen atoms derived from three different timb

308 ligands and three oxygen atoms from two different TBDC²⁻ ligands and one water

309 molecule. The coordination geometry of the Ni(II) center is a slightly distorted

310 octahedron with coordination angles ranging from 85.22(10)° to 175.26(11)° and the

311 Ni–O/N bond lengths varying from 2.040(2) to 2.144(3) Å (Table S1). Each timb

312 ligand in turn connects three Ni(II) atoms which form a triangle with edge lengths

313 (Ni···Ni) of 8.01, 10.58 and 13.29 Å, respectively. The three imidazolyl rings are

314 inclined to the phenyl ring with angles of 73.24°, 69.23° and 59.21°, respectively. As
315 shown in Fig. 4b, such a coordination mode makes the compound a 2D network with
316 a honeycomb structure, and a schematic drawing is shown in Fig. 4c. It is obvious that
317 all timb ligands in the network have *cis*, *trans*, *trans*-conformation with up- and
318 down-orientations alternatively. TBDC²⁻ ligands adopt monodentate and chelate
319 coordination modes and connect two Ni(II) atoms of the Ni-timb layers to generate a
320 2D structure (Fig. 4d). If the Ni(II) atom is considered as a five-connected node
321 (connecting to two TBDC anions and three timb ligands), the timb ligand can be
322 considered as a three-connected node (connecting to three Ni atoms), and the structure
323 of **4** can be classified as a rare (3,5)-connected 2D framework with (3.5²)(3².5³.6⁴.7)
324 topology (Fig. 4e). In addition, the 3D supramolecular structure of **4** is further
325 extended by C-H... π interactions.

326

327 <Figure 4 here>

328

329 **Crystal structure of Ni(TBDC)(bix)·H₂O (**5**)**

330 Single crystal X-ray diffraction analysis reveals that complex **5** crystallizes in the
331 triclinic space group *P*-1 and the asymmetric unit of **5** is constructed from one Ni(II)
332 ion, one fully deprotonated TBDC²⁻ ligand, one and a half bix ligands and one lattice
333 water molecule (Fig. 5a). The Ni(II) ion is coordination by three carboxylic oxygen
334 atoms from two different TBDC²⁻ ligands and three imidazolyl nitrogen atoms from
335 three bix ligands in a slightly distorted [NiO₃N₃] octahedral geometry. The three

336 coordinated carboxyl oxygen atoms together with two imidazolyl nitrogen atoms
337 define the equatorial positions, while the axial positions are occupied by two
338 imidazolyl nitrogen atoms. The Ni–O bond distances are in the range of 2.016(2)–
339 2.234(2) Å while the Ni–N bond distances are in the range of 2.048(3)–2.092(3) Å,
340 which are all in good agreement with those reported for other nickel–oxygen and
341 nickel–nitrogen donor compounds.²⁹ The TBDC²⁻ ligand exhibit η^2 - η^1 coordination
342 mode with one of the two carboxylate groups adopts chelating coordination mode
343 while the other one holds a monodentate bridging mode. The Ni(II) atoms are first
344 linked by the TBDC²⁻ linkers to form 1D chain as shown in Fig. 5b. Meanwhile, the
345 Ni(II) centers are also bridged by bix ligands to form 2D layers with (6, 3) topology as
346 shown in Fig. 5c. Then these chains and layers are cross-connected with each other to
347 form five-connected 3D framework with (4⁶.6⁴)-**bnn** hexagonal BN topology in which
348 the Ni(II) ions act as unimodal center (Fig. 5d). Further investigation into the topology
349 of complex **5** reveals that there are two identical independent 3D networks that
350 interpenetrate with each other (Fig. 5e). The two 3D subunits are related to each other
351 by one translation. In a word, the structure of **5** exhibits a 3D coordination network
352 with two-fold interpenetration of subunits with (4⁶.6⁴)-**bnn** hexagonal BN topology.

353

354

<Figure 5 here>

355

356 **Crystal structure of Ni(TBDC)(mbix)(H₂O)·H₂O (6)**

357 In order to investigate the influence of auxiliary ligand on the structure of the

358 complexes, reactions of $\text{Ni}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ with H_2TBDC in the presence of mbix were
359 carried out and complex **6** was obtained. As displayed in Fig. 6a, the asymmetric unit
360 of **6** contains crystallographically unique Ni(II) ion, one TBDC anion, one mbix
361 ligand, one coordinated water molecule and one lattice water molecule. The Ni(II)
362 center is six-coordinated by three carboxylate oxygen atoms from two individual
363 TBDC anions, two nitrogen atom from two different mbix ligands and one water
364 molecule, displaying a distorted octahedral coordination geometry. Each TBDC anion
365 links two Ni(II) ions with its two carboxylate groups adopting monodentate and
366 bidentate chelating modes. The mbix ligands connected adjacent Ni(II) ions to afford
367 a 1D zigzag chain. If mbix ligands are neglected, Ni(II) ions are bridged by TBDC
368 anions to form a 1D wavelike chain. The two types of chains are linked to generate
369 2D layers through sharing the central Ni(II) ions. Notably, the network has large
370 rhombic windows with approximate dimensions of $9.00 \times 20.60 \text{ \AA}^2$ built up by four
371 Ni(II) ions, two mbix ligands, and two TBDC anions within the 2D motif (Fig. 6b).
372 For convenience, if Ni(II) ions are viewed as uninodal 4-connected nodes, and TBDC
373 anions and mbix ligands are viewed as linkers, the layer can be described as a
374 4-connected **sql** topology with the point Symbol of $4^4.6^2$ (Fig. 6c). In addition, there
375 exist π - π stacking interactions associated with phenyl rings of TBDC anions and
376 phenyl rings of mbix ligands (face-to-face distance of 3.85 \AA and centroid-to-centroid
377 distance of 3.63 \AA) in the adjacent layers. These π - π interactions among layers led
378 the 2D sheets to a 3D supramolecular architecture (Fig. 6d).

379

380 <Figure 6 here>

381

382 **Crystal structure of Ni(TBDC)(obix)(H₂O) (7)**

383 The crystallographic analysis reveals that **7** is a one-dimensional tubular structure. As
384 shown in Fig. 7a, the asymmetric unit contains one Ni(II) ion, one TBDC²⁻ anion, one
385 obix ligand and one coordinated water molecule. Each Ni(II) ion is six-coordinated by
386 four oxygen atoms from two different TBDC²⁻ anion and one water molecule, and two
387 nitrogen atoms from two obix ligands to form a distorted octahedral geometry and its
388 basal plane is occupied by four oxygen atoms, while the apical position is occupied by
389 two nitrogen atom. The Ni-O bond lengths are in the range of 2.0227(18) - 2.1634(18)
390 Å, the Co-N bond lengths are 2.071(2) - 2.086(2) Å and the coordination angles
391 around Co ion are in the range of 61.24(7) - 176.82(9)°. Two Ni(II) ions are linked by
392 a couple of obix ligands to form 24-membered {Ni₂(obix)₂} ring and the distance of
393 neighboring Ni(II) ions is about 5.284 Å as presented in Fig. 7b. The obix ligand
394 adopts a *cis*-conformation with the dihedral angle between the two imidazole rings of
395 58.57°. Two carboxylate groups of TBDC²⁻ ligand adopt monodentate and bidentate
396 chelating coordination mode and link to the neighboring {Ni₂(obix)₂} rings, giving a
397 one-dimensional tubular structure. The separation of neighboring Ni(II) ions is about
398 10.24 Å as illustrated in Fig. 7c. The packing structure of **7** shows a three-dimensional
399 supramolecular network derived from chains formed *via* intermolecular C-H...O
400 hydrogen bonds and weak π - π stacking interactions (the centroid-to-centroid distance
401 of 4.125 Å between the two adjacent benzene rings of TBDC ligands and benzene

402 rings of obix ligands, and the dihedral angle is $5.302(5)^\circ$.

403

404

<Figure 7 here>

405

406 In this work, we selected imidazole-containing ligands and three different aromatic
407 dicarboxylates to construct seven target metal complexes, aiming at examining the
408 effect of substituent groups, the number of the carboxylic groups as well as the
409 auxiliary ligands on the assembly and structures of the resulting products. Compared
410 with related structures in the literature, $\text{Co}_3(\text{BIPA})_3(\text{titmb})_2] \cdot 0.73\text{H}_2\text{O}$ (**8**) and
411 $\text{Ni}(\text{mbix})(\text{BDC})(\text{H}_2\text{O})$ (**9**) (H_2BIPA = 5-bromoisophthalic acid).^{151,20b} In complexes **1**,
412 **4** and **8**, there exist the same metal coordination geometries and auxiliary ligand,
413 similar aromatic dicarboxylates and entirely different topological structures: a 3D
414 (3,5)-connected binodal $(6^3)(6^9.8)$ topology framework for **1**, a 2D (3,5)-connected
415 $(3.5^2)(3^2.5^3.6^4.7)$ topology framework for **4** and a 3D (3,4)-connected coordination
416 framework with the topology of $(4.6.8)(4.62.8^3)(6.8^5)(6^2.8^3.10)(8^3)$ for **8**, which are
417 attributed to the effect of 5-substituent groups. Whereas complex **6** has a 2D lamella
418 structure with (4,4) topology, complex **9** exhibits a rare (3,5)-connected 3D network
419 with $(4^2.6^5.8^3)(4^2.6)$ topology. The presence of the noncoordinating groups in
420 dicarboxylate ligands changes their electronic and steric properties, which can
421 generate complexes different from those of the common dicarboxylate ligands. The
422 Ni(II) ions are bridged by 1,3-benzenedicarboxylates to form 1D chains in **1** and the
423 Ni(II) ions are linked through 1,3,5-benzenetricarboxylates to generate 3D network in

424 **3**, and the results in the changes of the number of the carboxylic group, finally, causes
425 the difference between the frameworks of **1** and **3**. In this study, complexes **4** - **7**
426 display a diversity of 1D, 2D and 3D frameworks, and the connectivities of the four
427 complexes are strongly related to the imidazole-containing ligands. As described
428 above, the imidazole-containing ligands serve as bridging ligands with nitrogen atoms
429 of the imidazole units coordinating to the metal atoms. In **4**, Ni(II) ions are linked by
430 *titmb* ligands to form a 2D network with a honeycomb structure; in **5**, the Ni(II)
431 centers are also bridged by *bix* ligands to form 2D layers with (6, 3) topology. In **6**,
432 Ni(II) centers are bridged by *mbix* ligands to form zigzag chains and helices
433 simultaneously; in **7**, Ni(II) ions are linked by *obix* ligands to form [Ni(*obix*)₂Ni]
434 dimers.

435 **Thermogravimetric analyses**

436 To estimate the stability of the coordination architectures of complexes **1** - **7**,
437 thermogravimetric analyses (TGA) were carried out. The experiments were performed
438 on samples consisting of numerous single crystals of **1-7** under a N₂ atmosphere with
439 a heating rate of 10 °C min⁻¹ (Fig. 8). The TGA curves show that first a weight loss
440 occurs in the range of 40-180 °C (obsd 8.20%, calcd 8.47%) for **1**, which corresponds
441 to the free water molecules, and indicating that there exist strong hydrogen-bonding
442 interactions among the water molecules. The second weight loss was observed from
443 290 to 600 °C (obsd 12.4%, calcd 13.0%), showing the departure of organic ligands.
444 Finally, the remaining weight corresponds to the oxidized metal. Complex **2** loses the
445 two lattice water molecules and three coordinated water molecules in the range of 40

446 – 198 °C (obsd 7.4% and calcd 7.7%). The removal of water at a high temperature is
447 attributed to the strong hydrogen-bonding interactions. Further weight loss occurs
448 from 267 to 570°C (obsd 70.0% and calcd 78.0%), indicating organic ligands loss and
449 complex decomposition. The final residual weight corresponds to that of Ni₂O₃ (obsd
450 14.5%, calcd 14.2%). The TGA curve of **3** reveals that no obvious weight loss was
451 observed until the temperature rose to 290°C. The anhydrous compound decomposes
452 from 290 to 600°C (obsd 75.8 %, calcd 78.3%), indicating the release of organic
453 components. For **4**, the weight loss before 160 °C corresponds to the release of
454 coordinated water molecules (obsd 2.89%, calcd 2.74%), and the weight loss between
455 230 and 620 °C is attributable to the departure of organic components (obsd 78.2%,
456 calcd 84.7%). The residual is oxidized metal (obsd 11.3 %, calcd 12.6 %). The TG
457 curve for **5** reveals that the first weight loss of lattice water molecules is observed
458 from room temperature to 165 °C (obsd 2.9%, calcd 2.8 %), which shows that there
459 exist strong hydrogen-bonding interactions between the water molecules at high
460 temperature. The second weight loss occurs in the range of 250–630 °C (obsd 78.5%,
461 calcd 84.6 %), revealing that the compound decomposes. Finally, the residual is Ni₂O₃
462 (obsd 13.2%, calcd 12.7%). The first weight loss for complex **6** from 45 to 177 °C
463 corresponds to the elimination of one lattice water and one coordinated water (obsd
464 6.4% and calcd 6.5%). The second weight loss occurs between 210-620 °C (obsd
465 76.2%, calcd 78.5%), which may be assigned to the removal of organic ligands. After
466 that, the weight loss is slow, and finally yields the residual oxidised metal at 620 °C
467 (obsd 16.2% and calcd 15.0%). The TGA curve for **7** shows that a weight loss of 3.6%

468 occurs in range of 80–172 °C, which may be attributed to the removal of one
469 coordinated water molecule (obsd 3.1% and calcd 3.4%). Further, a weight loss occurs
470 in the range of 295–620 °C (obsd 76.9%, calcd 82.0%). There is no mass loss from
471 190 to 290 °C, indicating a relatively higher thermal stability.

472

473 **SHG response**

474 As mentioned in the introduction, CPs show interesting non-linear optical properties
475 (NLO) and second harmonic generation (SHG) responses. SHG is completely
476 dependent on crystal symmetry and SHG materials have been extensively applied to
477 high technique fields such as laser devices and optical communications. Generally, an
478 SHG-active material must require the absence of a symmetric center. Lin, Xiong,
479 Chen and coworkers illustrated that CPs with noncentrosymmetric structures can be
480 rationally designed and prepared by making use of metal ions with specific
481 geometries and high directional coordination bonds.³⁰ Thus, rationally designing and
482 synthesizing CPs with SHG responses has enabled us to understand the relationships
483 between structures and properties. Considering that complexes **1**, **3** and **4** crystallize
484 in the acentric space group ($Pna2_1$, $P2_13$ or $P2_12_12_1$), their nonlinear optical properties
485 were studied.³¹ The strength of the second harmonic generation (SHG) efficiency of
486 complexes **1**, **3** and **4** was tested by measuring the microcrystalline powder samples
487 with 61–90 μm in diameters. Preliminary examinations indicate that complexes **1**, **3**
488 and **4** are SHG-active and the SHG efficiency is approximately 0.8, 0.6, and 0.7 times
489 that of urea, respectively, which indicates that complexes **1**, **3** and **4** have potential

490 application in optical material. The modest powder SHG response of complexes **1**, **3**
491 and **4** may be attributed to a comparatively short donor–acceptor system, which is
492 essential for second-order optical nonlinearity.

493 Recently, a prevalent research has focused on developing ferroelectric materials
494 based on coordination polymers (CPs) and have reported some such materials.³²
495 However, the reported ferroelectric materials are mostly built upon chiral organic
496 tectons, whereas the proper use of achiral ligands by spontaneous are scarce.³³ Herein,
497 we describe the preliminary investigation of the possible ferroelectric property of
498 complex **1**. Complex **1** crystallizes in the acentric space group $Pna2_1$, which belongs
499 to the polar point group C_{2v} , which falls in one of the 10 polar point groups ($C1$, Cs ,
500 $C2$, $C2v$, $C4$, $C4v$, $C3$, $C3v$, $C6$, $C6v$) required for ferroelectric materials. Therefore,
501 the ferroelectric behavior of **1** was examined. Fig. 9 clearly shows that there is an
502 electric hysteresis loop that is a typical ferroelectric feature with a remanent
503 polarization (P_r) of *ca.* $0.049 \mu\text{C cm}^{-2}$ and coercive field (E_c) of *ca.* 850 V cm^{-1} . The
504 saturation spontaneous polarization (P_s) of **1** is *ca.* $0.21 \mu\text{C cm}^{-2}$, which is slightly
505 lower than that of Rochelle salt ($\text{NaKC}_4\text{H}_4\text{O}_6 \cdot 4\text{H}_2\text{O}$, $P_s = 0.25 \mu\text{C cm}^{-2}$).³⁴ The value
506 of P_s is comparable to that of some CPs reported in the literature.³⁵ Furthermore, we
507 also studied the behavior of permittivity (ϵ) = $\epsilon_1(\omega) - i\epsilon_2(\omega)$, where $\epsilon_1(\omega)$ and $i\epsilon_2(\omega)$
508 are the real (dielectric constant) and imaginary (dielectric loss) parts, respectively. The
509 results reveal that the frequency dependence of the dielectric constant ϵ_1 at room
510 temperature (20 °C) indicates that ϵ_1 rapidly decreases with the increase of frequency,
511 while dielectric loss remains unchanged.

512

513

<Figure 8 here>

514

515 Conclusions

516 In this work, we have successfully fabricated seven novel coordination polymers
517 under hydrothermal condition. Complex **1** shows a three-dimensional (3D)
518 (3,5)-connected network with the topology of $(6^3)(6^9.8)$. Complexes **2** and **6** have
519 similar two-dimensional (2D) lamella structure with (4,4) topology. Complex **3**
520 exhibits an interesting 3D (3,6)-connected framework by self-penetration of two sets
521 of (10,3)-a nets. Complex **4** presents a unusual 2D (3,5)-connected framework with
522 the topology of $(3.5^2)(3^2.5^3.6^4.7)$. Complex **5** features a 3D two-fold interpenetrating
523 framework with $(4^6.6^4)$ -**bnn** hexagonal BN topology, whereas Complex **7** possesses
524 an interesting one-dimensional (1D) independent single-wall metal-organic nanotube.
525 The various dimensions and structural features of the seven complexes may be
526 attributed to the different species of functional groups, the number and position of the
527 carboxylic groups in the carboxylates as well as the auxiliary ligands. Additionally,
528 the ferroelectric and NLO properties of the imidazole and carboxylate system have
529 been investigated, and open up a new avenue to NLO and ferroelectric materials
530 through CPs.

817 **Captions for Scheme and Figures:**

818

819 **Scheme 1** Structures of imidazole-containing ligands and polycarboxylates used in
820 this work.

821 **Fig. 1** (a) Coordination environment of Ni(II) ions in **1** with the ellipsoids drawn at
822 the 30% probability level; hydrogen atoms and water molecules were omitted for
823 clarity. Symmetry codes: A $-x+3/2, y-1/2, z-1/2$; B $x-1/2, -y-1/2, z$; C $x, y-1, z$. (b)
824 Ball-stick representation of the Ni-titmb sheet in **1**. (c) Schematic representation of the
825 2D (6,3) framework. (d) Stick representation of a 3D structure of **1** along the c -axis. (e)
826 Schematic view of the $(6^3)(6^9.8)$ topology.

827 **Fig. 2** (a) Coordination environment of Ni(II) ions in **2** with the ellipsoids drawn at
828 the 30% probability level; hydrogen atoms were omitted for clarity. Symmetry codes:
829 A $x-1, y, z$; B $x+1, y, z+1$. (b) Molecular packing of the sub-layer in **2**. (c)The
830 square-like network of **2**. Only the nickel atoms and the connections between them are
831 shown. The orientation of the diagram is along a -axis. (d)View of the 3D
832 hydrogen-bonding network in the packing of **2** along the c axis; O–H \cdots O interactions
833 are shown as dashed lines.

834 **Fig. 3** (a) Coordination environment of Ni(II) and Zn(II) ions in **3** with the ellipsoids
835 drawn at the 30% probability level; hydrogen atoms were omitted for clarity.
836 Symmetry codes: A y, z, x ; B z, x, y ; C y, z, x ; D z, x, y . (b) Heterometallic binuclear
837 ZnNi(CO₂)₃Br unit observed for **3**. (c) Schematic representation of the (10,3)-a net in
838 **3** along the c -axis; the binuclear units are represented by the green balls and the BTC³⁻
839 anions are represented by the blue nodes. (d) Schematic representation of the second

840 (10,3)-a net in **3** along the *c*-axis; the binuclear units are represented by the purple
841 balls and the titmb ligands are represented by the yellow nodes. (e) Schematic
842 representation of the overall network topology in complex **3**; titmb and BTC^{3-} ligands
843 are represented by yellow and blue nodes, respectively.

844 **Fig. 4** (a) Coordination environment of Ni(II) ions in **4** with the ellipsoids drawn at
845 the 30% probability level; hydrogen atoms and water molecules were omitted for
846 clarity. Symmetry codes: A $-x+1, y-1/2, -z+1/2$; 2; B $-x, y+1/2, -z+1/2$; C $-x+1, y+1/2, -z+1/2$.
847 (b) Ball-stick representation of the Ni-titmb sheet in **4**. (c) Schematic representation of
848 the 2D (6,3) framework. (d) Stick representation of a 3D structure of **4** along the
849 *c*-axis. (e) Schematic view of the $(3.5^2)(3^2.5^3.6^4.7)$ topology.

850 **Fig. 5** (a) Coordination environment of Ni(II) ions in **5** with the ellipsoids drawn at
851 the 30% probability level; hydrogen atoms and water molecules were omitted for
852 clarity. Symmetry codes: A $x, y-1, z$; B $-x, 2-y, 2-z$; C $-1-x, 1-y, 1-z$; D $1-x, 2-y, 1-z$. (b)
853 View of the 1D chain of Ni(II) linked by TBDC^{2-} anion in **5**. (c) View of the (6, 3)
854 layer of Ni(II) bridged by bix ligands; (d) View of the 3D framework with $(4^6.6^4)\text{-bnn}$
855 hexagonal BN topology. (e) Schematic illustration of the two-fold interpenetration
856 network in **5**.

857 **Fig. 6** (a) Coordination environment of Ni(II) ions in **6** with the ellipsoids drawn at
858 the 30% probability level; hydrogen atoms were omitted for clarity. Symmetry codes:
859 A $x, y-1, z$; B $x+1, y-1, z$. (b) View of 2D layer constructed by Ni(II) ions, TBDC
860 anions, and mbix ligands. (c) Schematic representation of topology of **6** (the green
861 spheres represent the Ni(II) ions and blue and purple lines represent the mbix ligands

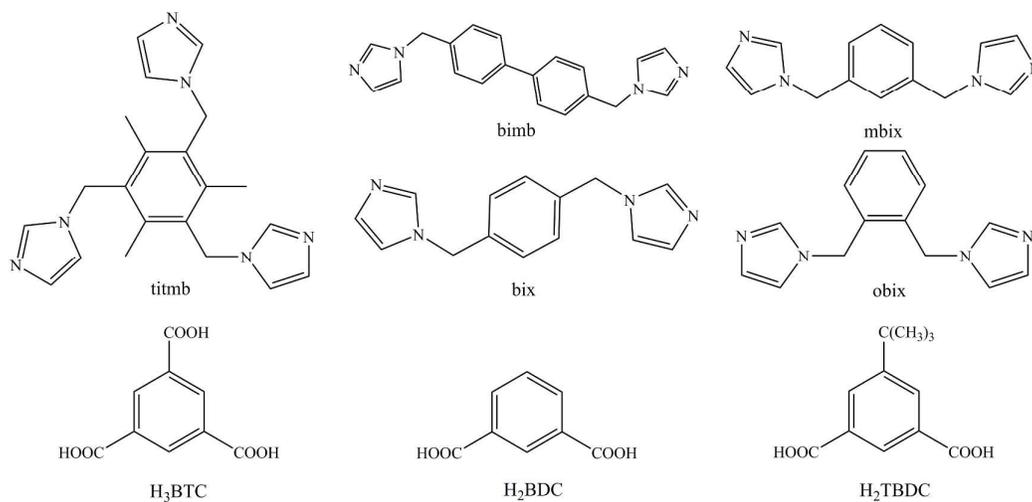

862 and TBDC anions, respectively). (d) The 3D supramolecular network constructed by
863 π - π interactions in **6**.

864 **Fig. 7** (a) Coordination environments of the Ni(II) atoms in **7** with the ellipsoids
865 drawn at the 30% probability level; hydrogen atoms were omitted for clarity.
866 Symmetry codes: A $x+1, y, z$; B $-x+1, -y+1, -z$. (b) View of 24-membered $[\text{Ni}_2(\text{obix})_2]$
867 ring in **7**. (c) Schematic representation of the 1D tubular structure in **7**.

868 **Fig. 8** TGA curves of complexes **1** – **7**.

869 **Fig. 9** Electric hysteresis loops of complex **1** under different voltages at room
870 temperature.

Graphical Abstract:

Seven nickel(II) coordination polymers, based on varied polycarboxylates and different imidazole-containing ligands, are obtained, indicating that the different species of functional groups, the number and position of the carboxylic groups in the carboxylates as well as the auxiliary ligands have crucial influences on the final structures.
