This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. This Accepted Manuscript will be replaced by the edited, formatted and paginated article as soon as this is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
Ytterbium and erbium co-doped sodium yttrium fluoride (NaYF$_4$: Er$^{3+}$, Yb$^{3+}$) rare-earth upconversion nanoparticles (UCNPs) with α and β phases were prepared. UCNPs with core-shell structure were prepared and modified to be hydrophilic by ligand-free hydrophilic modification.
Synthesis and characterization of upconversion nanoparticles with shell structure and ligand-free hydrophilic modification

Di Kang†, Xiaoyan Song†b and Jinfeng Xing*a

Ytterbium and erbium co-doped sodium yttrium fluoride (NaYF4: Er3+, Yb3+) rare-earth upconversion nanoparticles (UCNPs) with different phases were prepared and characterized. The luminescence intensity of UCNPs can be enhanced by coating a uniform layer of the shell. The crystal structure, morphology and upconversion spectra of the sample were investigated using X-ray powder diffractometer, transmission electron microscope, and laser upconversion spectrometer with 980 nm diode laser. Finally, UCNPs with core-shell structure were modified to be hydrophilic by ligand-free hydrophilic modification. Moreover, the water dispersible UCNPs have much stronger luminescence compared with hydrophobic UCNPs.

1 Introduction

Rare-earth upconversion nanoparticles (UCNPs) excited by near-infrared light exhibit a unique narrow photoluminescence with higher energy,1, 2 in which the low-energy photons transfer into a higher-energy photons through a multi-step.3 Compared with the conventional down-conversion material such as organic dyes and quantum dots (QDs), UCNPs have several advantages such as high light penetration depth in tissues, no photo-damage to living organisms, weak autofluorescence from cells or tissues, low background light, high sensitivity for detection, minimal photobleaching and low phototoxicity.4-6 Therefore, UCNPs can be applied in various biomedical applications, including immunoassays, biomedical imaging, molecular sensing, X-ray computed tomography (CT), and photodynamic therapy (PDT).3, 7-10 UCNPs with high-quality are important to meet biomedical applications. UCNPs are composed of three components including a host matrix, a sensitizer and an activator. An ideal host matrix should have low lattice photon energies as a prerequisite to minimize non-radiative losses and maximize the radiative emission.11 Among the available types of upconversion host materials, fluoride such as NaYF4 was proved to be the best choice due to their relatively low phonon energy and excellent chemical stability.12-14 Most of the attention has been focused on the synthesis of high-quality nanoparticles such as cubic (α-) and hexagonal (β-) NaYF4.15-18 In all of the upconversion materials, cubic (α-) and hexagonal (β-) NaYF4 have been reported as the most efficient UCL host materials, especially for Yb3+/Er3+ upconversion systems.18-20 However, the properties of the upconversion nanoparticles are not only determined by their phase, but also by their structure, size, morphology, synthesis process and composition.17, 21 Therefore, it needs to have a deeper analysis and comparison of cubic (α-) and hexagonal (β-) NaYF4. It was confirmed that luminescence of upconversion nanoparticles can be enhanced only by adjusting phases but also by coating shell.22, 23 Usually, synthetic approaches for UCNPs involved the use of organic capping ligands. Therefore, UCNPs are hydrophobic.21, 24-27 Due to the hydrophobicity of UCNPs, they are hard to be applied in biomedical field. Several strategies to develop water dispersible UCNPs have been reported such as encapsulation by SiO228-30 ligand exchange,31 ligand oxidation reaction,32 and surface modification.33, 34 However, the precise control over the thickness and shape of the encapsulating SiO2 layer are difficult to be precisely controlled, resulting in a relatively larger hydrodynamic particle radius.35 The methods of Ligand exchange and ligand oxidation are limited to a specific class of UCNPs capped with ligand molecules containing unsaturated carbon-carbon bonds in their long alkyl chains.11 Ligand-free has recently been used to prepare water dispersible UCNPs, the UCNPs obtained are uniform, which is a convenient, safe and low-cost method to remove the oleate ligand and to
obtain highly water dispersible UCNPs with strong luminescence. In this study, two phases of ytterbium and erbium co-doped sodium yttrium fluoride nanoparticles (NaYF₄: Er³⁺, Yb³⁺) were prepared to examine their luminescence properties, size and morphology under different synthetic conditions. To further enhance the luminescence intensity, UCNPs with core-shell structure were modified to be hydrophilic by ligand-free hydrophilic modification. Importantly, the water dispersible UCNPs have much stronger luminescence compared with hydrophobic UCNPs.

2 Experimental

2.1 Materials

All chemicals were of analytical grade and used as received without further purification. Deionized water was used throughout. Y(CH₃COO)₃ (99.9% trace metals basis), Yb(CH₃COO)₃ (99.9% trace metals basis) and Er(CH₃COO)₃ (99.9% trace metals basis) were supplied by Sigma-Aldrich. Oleic acid (technical grade, 90%), 1-Octadecene (technical grade, 90%) and NaOH (reagent grade, ≥98%) were supplied by Aldrich. Methanol (reagent grade, ≥99.5%), Ethanol (reagent grade, ≥99.7%), Cyclohexane (reagent grade, ≥99.5%) and HCl (technical grade, 90%), 1-Octadecene (technical grade, 90%) were supplied by Aladdin Chemical Company. Methanol (reagent grade, ≥99.5%), Ethanol (reagent grade, ≥99.7%), Cyclohexane (reagent grade, ≥99.5%), HCl (reagent grade, ≥99.5%), Acetone (reagent grade, ≥99.5%), Ethyl ether (reagent grade, ≥99.5%) and NH₄F (ACS reagent, ≥98%) were purchased from Jiangtian Chemical Technology Co.,Ltd (Tianjin China).

2.2 Synthesis of α-NaYF₄: Er³⁺, Yb³⁺ and β-NaYF₄: Er³⁺, Yb³⁺ Nanocrystals

Firstly, a water solution (3 mL) containing Y(CH₃COO)₃ (0.4 mmol), Yb(CH₃COO)₃ (0.392 mmol) and Er(CH₃COO)₃ (0.008 mmol) was added to a 50 mL flask containing oleic acid (8 mL) and 1-octadecene (12 mL). Then the mixture was heated at 150 °C while stirring for 1 h to form lanthanide oleate complexes and remove water and then cooled down to room temperature. Subsequently, a methanol solution (8.8 mL) containing NH₄F (2.64 mmol) and NaOH (2 mmol) was added and stirred at 50 °C for 1 h. After the reaction temperature was increased to 100 °C, the methanol and water were removed from the reaction mixture. Then the solution was heated to 300 °C and maintained at this temperature under an argon atmosphere for 1.5 h or 2.0 h, and then the mixture was cooled down to room temperature. The resulting nanoparticles were precipitated out through an addition of ethanol, collected by centrifugation, washed with ethanol, and finally redispersed in 8 mL of cyclohexane.

2.3 Synthesis of β-NaYF₄: Er³⁺, Yb³⁺ Nanocrystals

Firstly, a water solution (3 mL) containing Y(CH₃COO)₃ (0.8 mmol), Yb(CH₃COO)₃ (0.18 mmol) and Er(CH₃COO)₃ (0.02 mmol) was added to a 50 mL flask containing oleic acid (6 mL) and 1-octadecene (15 mL). Then the mixture was heated at 150 °C while stirring for 1 h to form lanthanide oleate complexes and remove water and then cooled down to room temperature. Subsequently, a methanol solution (8.8 mL) containing NH₄F (2.64 mmol) and NaOH (2 mmol) was added and stirred at 50 °C for 1 h. After the reaction temperature was increased to 100 °C, the methanol and water were removed from the reaction mixture. Then the solution was heated to 300 °C or 320 °C and maintained at this temperature under an argon atmosphere for 1.5 h or 2.0 h, and then the mixture was cooled down to room temperature. The resulting nanoparticles were precipitated out through an addition of ethanol, collected by centrifugation, washed with ethanol, and finally redispersed in 8 mL of cyclohexane.

2.4 Synthesis of NaYF₄:Er³⁺, Yb³⁺ @NaYF₄ Nanospheres

A water solution (2 mL) containing Y(CH₃COO)₃ (0.4 mmol) was added to a 50 mL flask containing oleic acid (6 mL) and 1-octadecene (15 mL). The mixture was then heated at 150 °C for stirring for 1 h and then cooled down to 50 °C. The β-NaYF₄: Er³⁺, Yb³⁺ nanospheres in cyclohexane were added along with a 6 mL methanol solution of NH₄F (1.76 mmol) and NaOH (1.1 mmol). The resulting mixture was stirred at 50 °C for 1 h, and then the reaction temperature was increased to 100 °C to remove the methanol and cyclohexane. After that the solution was heated at 300 °C under an argon flow for 1.5 h and then cooled to room temperature. The resulting nanoparticles were precipitated out by the addition of ethanol, collected by centrifugation, washed with ethanol, and redispersed in cyclohexane.

2.5 Synthesis of water dispersible NaYF₄:Er³⁺, Yb³⁺ @NaYF₄ Nanospheres

Water dispersible β-NaYF₄: Er³⁺, Yb³⁺ @NaYF₄ nanospheres were obtained by the previously reported strategy. The β-NaYF₄: Er³⁺, Yb³⁺ @NaYF₄ nanospheres were dispersed in a 10 mL aqueous solution. The reaction was performed with stirring for 2 h while maintaining the pH at 4 by adding a solution of 0.1 M HCl. After the reaction was completed, the mixture solution was extracted with diethyl ether for three times. The resulting nanoparticles were precipitated out by the addition of acetone, collected by centrifugation and redispersed in deionized water.

2.6 Characterization

The phase purity of the products was examined by Powder X-ray diffraction (XRD) on D8-Focus using Cu Kα radiation (λ=1.5406 Å). The size and morphology of the nanocrystals were determined by JEM-2100F transmission electron microscope (TEM) at 200 kV. Samples were prepared by placing a drop of a dilute cyclohexane dispersion of nanocrystals on the surface of a copper grid. UC emission spectra were obtained using 980 nm diode laser with a 0.75 W/cm² of laser power density (UCNPs concentration is 1 wt % in cyclohexane or water). The ²H NMR spectrum of oleic acid and the oleate-capped NaYF₄: Er³⁺, Yb³⁺ @NaYF₄ Nanospheres dispersed in CDC₁₃ and the oleate-free NaYF₄: Er³⁺, Yb³⁺ @NaYF₄ Nanospheres dispersed in D₂O were recorded on 500 MHz (Varian INOVA) NMR spectrometer as solvent containing a small amount of TMS as internal standard. FTIR spectra were performed on a WQF-510A instrument using the pressed KBr pellet.
3 Results and Discussion

3.1 Characterization of α-NaYF₄: Er³⁺, Yb³⁺ and β- NaYF₄: Er³⁺, Yb³⁺ Nanocrystals

Fig. 1 shows the powder XRD patterns of cubic (α-) and hexagonal (β-) NaYF₄: Er³⁺, Yb³⁺ UCNPs prepared at different reaction time. When the reaction time was 1 h, all the diffraction peaks could be indexed to those of a pure phase-cubic NaYF₄ crystal structure (ICPDS standard card No. 27-1426), indicating that cubic (α-) NaYF₄: Er³⁺, Yb³⁺ UCNPs were prepared. When the reaction time reached 1.5 h, transformation of NaYF₄ nanocrystals from α- to β-phase appeared. The X-ray diffraction pattern of NaYF₄: Er³⁺, Yb³⁺ samples could be indexed as a mixture of the cubic (ICPDS standard card No. 27-1426) and hexagonal (ICPDS standard card No. 28-1192) phases of NaYF₄, demonstrating that the transformation from cubic to hexagonal indeed occurred. The pure hexagonal phase of NaYF₄ was obtained as the reaction time prolonged to 1.7 h (ICPDS standard card No. 28-1192).

![Fig. 1 XRD patterns of NaYF₄: Er³⁺, Yb³⁺ nanocrystals prepared at different reaction time as well as the standard ICPDS No. 27-1426 of α-NaYF₄: Er³⁺, Yb³⁺ (red line) and ICPDS No. 28-1192 of β-NaYF₄: Er³⁺, Yb³⁺ (black line) (Note that Cu Kα radiation was used for the XRD measurement).](image1)

Fig. 2A-C exhibits the TEM images of cubic (α-) and hexagonal (β-) NaYF₄: Er³⁺, Yb³⁺ UCNPs prepared at 300 °C with various reaction times from 1 h to 1.7 h. It can be observed that all of the nanoparticles have a uniform particle size around 43 nm and good monodisperse. The morphology of UCNPs translates from cube to hexagon with reaction time increasing. When the reaction time reaches 1.5 h, the translation of UCNPs from cube to hexagon obviously occurs. In the UCNPs with cubic structure, the cation sites are equal and the Na and Y atoms randomly distribute in the cationic sublattice, while in the UCNPs with hexagonal structure, there are three different cation sites. Therefore, cubic α-phase is a metastable high-temperature phase and hexagonal β-phase is a thermodynamically stable low-temperature phase. The transformation process from the cubic phase to hexagonal phase is one evolving from disorder to order process, indicating that the transformation from cubic to hexagonal phase is the thermodynamic process and the transformation of disorder to order is a process of growth kinetics. Under 980 nm laser excitation, Er³⁺ ions in NaYF₄ nanocrystals exhibit dual emission bands (green and red). Upconversion spectra of NaYF₄: Er³⁺, Yb³⁺ UCNPs prepared at different reaction time for 300 °C are shown in Fig. 2D. Three emissions bands around 520, 540 and 650 nm are ascribed to \( ^{1}I_{15/2} \rightarrow ^{3}H_{11/2}, ^{1}S_{0} \rightarrow ^{1}I_{15/2} \) and \( ^{2}F_{9/2} \rightarrow ^{1}I_{15/2} \) transitions of Er³⁺ ion, respectively. It can be clearly observed that the relative intensity of emissions (520 nm, 540 nm and 650 nm) varies with the reaction time. The luminescence intensity of UCNPs increases with the reaction time. It is suggested that the luminescence intensity can be enhanced by prolonging the reaction time due to the increase of β-NaYF₄. It was confirmed that the crystal structure of the β-phase favours the emission of the dopant ions more than that of the α-phase. Naturally, β-NaYF₄ has a stronger luminescence intensity.

![Fig. 2 TEM images of NaYF₄: Er³⁺, Yb³⁺ UCNPs prepared at different reaction time for 300 °C. (A)1.0 h; (B)1.5 h; (C)1.7 h; (D) Upconversion spectra of NaYF₄: Er³⁺, Yb³⁺ UCNPs prepared at different reaction time for 300 °C. All of nanoparticles were excited at 980 nm with a diode laser.](image2)

3.2 Characterization of β-NaYF₄: Er³⁺, Yb³⁺ Nanospheres

The x-ray diffraction (XRD) pattern results of the β-NaYF₄: Er³⁺, Yb³⁺ nanospheres are shown in Fig. 3. All the diffraction peaks could be indexed to a pure phase-hexagonal NaYF₄ nanospheres structure (ICPDS standard card No. 28-1192). No diffraction peaks corresponding to cubic phases or other impurities appear, indicating the successful synthesis of pure hexagonal-phase NaYF₄ nanospheres. Moreover, it can be deduced that the β-NaYF₄: Er³⁺, Yb³⁺ nanospheres own highly crystalline in nature from the intensity of the peaks. Furthermore, as shown in Fig. 3, comparing with samples at different reaction temperature, it can be found that the crystalline of β-NaYF₄: Er³⁺, Yb³⁺ nanospheres could be improved by increasing reaction temperature or prolonging reaction time. However, there is no influence on the phase of β-NaYF₄: Er³⁺, Yb³⁺ nanospheres.
3.4 Characterization of water dispersible NaYF₄: Er³⁺, Yb⁵⁺@NaYF₄ Nanospheres

To achieve water dispersible NaYF₄: Er³⁺, Yb⁵⁺@NaYF₄ nanoparticles, the oleate-capped NaYF₄: Er³⁺, Yb⁵⁺@NaYF₄ nanoparticles were modified with a simple Ligand-free method. The UCNPs could exist stably in water for one week. The UCNP spectra of oleate, oleate-capped NaYF₄: Er³⁺, Yb⁵⁺@NaYF₄ nanoparticles and water dispersible NaYF₄: Er³⁺, Yb⁵⁺@NaYF₄ nanoparticles are shown in Fig. 6A. It can be found that the oleate ligand is completely removed from oleate-capped NaYF₄: Er³⁺, Yb⁵⁺@NaYF₄ nanoparticles through ligand-free method. FTIR spectra of oleate, oleate-capped NaYF₄: Er³⁺, Yb⁵⁺@NaYF₄ nanoparticles and water dispersible NaYF₄: Er³⁺, Yb⁵⁺@NaYF₄ nanoparticles are shown in Fig. 6B. The transmission bands at 2929 and 2855 cm⁻¹ are attributed to the asymmetric and symmetric stretching vibrations of methylene groups (CH₂) in the long alkyl chain of OA. Two bands at 1458 and 1568 cm⁻¹ in OA-UCNPs are attributed to the asymmetric and the symmetric stretches of -COO⁻.
characteristic bands corresponding to OA almost disappear, demonstrating that OA was removed from the surface of UCNPs. Fig. 6c shows the upconversion emission spectra of NaYF\(_4\) \(\text{Er}^{3+}\), Yb\(^{3+}\)@NaYF\(_4\) nanospheres in water. NaYF\(_4\) \(\text{Er}^{3+}\), Yb\(^{3+}\) UCNPs exhibit emissions bands around 520, 540 and 650 nm, which were ascribed to \(^3\text{H}_{11/2} \rightarrow ^3\text{I}_{5/2}\), \(^3\text{S}_2 \rightarrow ^3\text{I}_{4/2}\) and \(^1\text{F}_2 \rightarrow ^3\text{I}_{5/2}\) transitions of \(\text{Er}^{3+}\) ion and the peak positions remain the same. Notably, luminescent intensity for the oleate-free nanoparticles in water increases probably due to absence of the surface oleate. The reason is that organic ligands with high energy C=H or C=C vibrations may lead to fluorescent quenching for nearby lanthanide ions.\(^5\)

4 Conclusions

Two phases of ytterbium and erbium co-doped sodium yttrium fluoride nanoparticles (NaYF\(_4\) \(\text{Er}^{3+}\), Yb\(^{3+}\)) were synthesized and their luminescence properties, size and morphology under different synthesis conditions were examined. The transformation from the cubic phase to hexagonal phase occurs with the reaction time increasing. \(\beta\)-NaYF\(_4\) \(\text{Er}^{3+}\), Yb\(^{3+}\) have a stronger luminescent intensity than \(\alpha\)-NaYF\(_4\) \(\text{Er}^{3+}\), Yb\(^{3+}\). Upconversion nanoparticles with core-shell structure were prepared to improve their luminescence intensity. The quenching effects can be strongly suppressed by coating a uniform layer of the shell. Finally, water dispersible upconversion nanoparticles with high luminescent intensity were successfully prepared with ligand-free hydrophilic modification.
