## Graphical Abstract

The efficiency of DSSCs with CoMoO<sub>4</sub>/Co<sub>9</sub>S<sub>8</sub> CEs was 8.60% under the light intensity of 100  $\text{mW cm}^{-2}$  (AM 1.5 G).

# Hydrothermal synthesis of CoMoO<sub>4</sub>/Co<sub>9</sub>S<sub>8</sub> hybrid nanotubes based on counter electrodes for high efficient dye-sensitized solar Cells

Jinghao Huo, Jihuai Wu\*, Min Zheng, Yongguang Tu, Zhang Lan

Education, Institute of Materials Physical Chemistry, Huaqiao University, Quanzhou 362021,  
China

**Abstract:** The CoMoO<sub>4</sub>/Co<sub>9</sub>S<sub>8</sub> hybrid nanotubes are fabricated by a simple  
two-step hydrothermal method, which was similar with preparing Co<sub>9</sub>S<sub>8</sub> nanotubes.  
10 Then CoMoO<sub>4</sub>/Co<sub>9</sub>S<sub>8</sub> nanotubes are coated on a fluorine-doped tin oxide glass to  
fabricate a counter electrode (CE) by spin-casting. Field emission scanning electron  
microscopy images show that the introduction of CoMoO<sub>4</sub> to Co<sub>9</sub>S<sub>8</sub> makes the surface  
of CoMoO<sub>4</sub>/Co<sub>9</sub>S<sub>8</sub> nanotubes rougher. The cyclic voltammetry shows that the  
electrocatalytic activity of CoMoO<sub>4</sub>/Co<sub>9</sub>S<sub>8</sub> CE is similar with Pt CE when the  
15 (NH<sub>4</sub>)<sub>2</sub>MoO<sub>4</sub> content was 60 wt%. Meanwhile the electrochemical impedance  
spectroscopy and Tafel measurements demonstrate that the CoMoO<sub>4</sub>/Co<sub>9</sub>S<sub>8</sub> CE had  
smaller values of R<sub>s</sub> and R<sub>ct</sub> than that of Pt CE. The dye-sensitized solar cells  
assembled with CoMoO<sub>4</sub>/Co<sub>9</sub>S<sub>8</sub> CE obtain excellent values of open-circuit voltage  
(0.743 V), short-circuit current density (17.276 mA cm<sup>-2</sup>), fill factor (0.670) and a  
20 wonderful power conversion efficiency (8.60%), which is higher than that of DSSCs  
with Co<sub>9</sub>S<sub>8</sub> CE (7.69%) or Pt CE (8.13%) under the light intensity of 100 mW cm<sup>-2</sup>  
(AM 1.5 G).

## 25 1. Introduction

Dye-sensitized solar cells (DSSCs) are a type of clean, low-cost and easily-fabricated equipment to convert solar energy into electricity [1-3]. Today many researchers try their best to explore the cheap and high efficient materials to fabricate DSSCs. In general, a DSSC includes three parts: a dye-sensitized photoanode  
30 (typically,  $\text{TiO}_2$ ), an electrolyte (typically,  $\text{I}_3^-/\text{I}^-$ ), and a counter electrode (CE). The role of CEs is to collect the electrons from photoanode by the external circuit and has a catalytic reaction for the reduction of  $\text{I}_3^-/\text{I}^-$  [3]. The metal of platinum is one of the most commonly used materials for CEs, while the characteristics of exorbitant price and easy corrosion limit its application [4]. Nowadays many other materials are as the  
35 candidate materials to fabricate the CEs of DSSCs, such as carbon materials [5-7], conducting polymers [8-10], alloys [11, 12], metal -oxide [13], -nitride [14], -sulfide [15, 16], -selenide [17, 18], -phosphide [19] and hybrid materials [20-22].

Cobalt sulfide is one kind of transition metal sulfide catalytic materials and it includes a variety of binary sulfides, such as  $\text{CoS}$ ,  $\text{CoS}_2$ ,  $\text{Co}_3\text{S}_4$ ,  $\text{Co}_9\text{S}_8$  and so on [23].  
40 Among these cobalt sulfides,  $\text{Co}_9\text{S}_8$  has attracted intense interest because of the complicated structure, interesting properties. Hence  $\text{Co}_9\text{S}_8$  was widely employed in hydrogenation and hydrodesulfurization [24], cathodic material for lithium batteries [25, 26], supercapacitors [27, 28] and other fields [29]. Based on its good catalytic activity, some researchers synthesized  $\text{Co}_9\text{S}_8$  to be CE materials of DSSCs. In 2013,  
45 Chang et. al [30] prepared a  $\text{Co}_9\text{S}_8$  nanocrystal ink by spray-deposited and the large area DSSCs with this  $\text{Co}_9\text{S}_8$  CE obtained a power conversion efficiency (PCE) of  $7.02 \pm 0.18\%$ , which was similar to that of DSSC with Pt CE ( $7.2 \pm 0.12\%$ ). Chen et. al [31]

fabricated a novel one-dimensional  $\text{Co}_9\text{S}_8$  acicular nanotube arrays (ANTAs) on a conducting plastic substrate by a two-step approach. With this  $\text{Co}_9\text{S}_8$  ANTAs as CEs, the DSSCs achieved a PCE of 5.47%, which was comparable to that of the DSSC using sputtered Pt (5.62%). In addition,  $\text{CoMoO}_4$  attracted researchers' attention due to its advantages of low cost, non-toxic, and exhibits enhanced electrochemical properties on lithium batteries [32] and supercapacitors [33, 34].

In this paper,  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$  hybrid nanotubes were synthesized by a two-step hydrothermal method. In the first step,  $\text{Co}(\text{CO}_3)_{0.35}\text{Cl}_{0.20}(\text{OH})_{1.10}$  nanoneedles were fabricated and used to be the templates of fabricating  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$  hybrid nanotubes [35]. The as-obtained hybrids could take advantage of the favorable property of  $\text{CoMoO}_4$  and  $\text{Co}_9\text{S}_8$ . Cyclic voltammetry (CV), electrochemical impedance spectroscopy (EIS) and Tafel tests proved that the  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$  CEs possessed good conductivity and catalytic activity for the reduction of  $\text{I}_3^-/\text{I}^-$ . With  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$  hybrid nanotubes as CEs, the DSSCs had a high current density ( $17.276 \text{ mA cm}^{-2}$ ) and an excellent PCE of 8.60%, which was higher than that of DSSCs with Pt CE (8.13%).

## 2. Experimental

### 2.1. Chemicals and materials

The cobalt chloride hexahydrate ( $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ ,  $\geq 99\%$ ), urea ( $\geq 99.0\%$ ), sodium sulfide nonahydrate ( $\text{Na}_2\text{S} \cdot 9\text{H}_2\text{O}$ ,  $\geq 98\%$ ), isopropyl alcohol (IPA,  $\geq 99.7\%$ ), titanium tetrachloride ( $\text{TiCl}_4$ , 99.9%), acetonitrile (ACN, 99.9%), tetraethyl ammonium iodide (98%), tetrabutyl ammonium iodide (99%), tetramethyl ammonium iodide (99%), 4-tert-butyl pyridine (tBP, 96%), lithium perchlorate ( $\text{LiClO}_4$ , 99.9%), sodium iodide ( $\text{NaI}$ ,  $>99\%$ ), potassium iodide (KI, 99%), lithium iodide ( $\text{LiI}$ , 99.5%), and iodine ( $\text{I}_2$ , 99%) were all A. R. grade and purchased from Sinopharm Chemical Reagent Co. Ltd,

China. Ammonium molybdate ((NH<sub>4</sub>)<sub>2</sub>MoO<sub>4</sub>, 99.99%) was purchased from Alfa Aesar. N719 dye (Ru[LL'-(NCS)<sub>2</sub>], L = 2, 2'-bipyridyl-4, 4'-dicarboxylic acid, L' = 2, 2'-bipyridyl-4, 4'-ditetrabutylammonium carboxylate) was acquired from Dye sol.

The fluorine-doped tin oxide (FTO) glass (14 Ω sq<sup>-1</sup>) was purchased from Wuhan Lattice Solar Energy Technology Co. Ltd, China. The FTO glass was cut into pieces (1.5×1.5 cm<sup>2</sup>) and washed with cleaner, acetone and IPA in turn and stored in anhydrous ethanol.

## 80 2.2. Synthesis of CoMoO<sub>4</sub>/Co<sub>9</sub>S<sub>8</sub> hybrid nanotubes

Scheme 1 here

The CoMoO<sub>4</sub>/Co<sub>9</sub>S<sub>8</sub> hybrid nanotubes were fabricated by the same two-step hydrothermal method as that of Co<sub>9</sub>S<sub>8</sub> (scheme 1). First, to prepare a precursor of Co(CO)<sub>0.35</sub>Cl<sub>0.20</sub>(OH)<sub>1.10</sub>·1.74H<sub>2</sub>O nanorods with CoCl<sub>2</sub>·6H<sub>2</sub>O and urea. In brief, 10 mmol of CoCl<sub>2</sub>·6H<sub>2</sub>O and 10 mmol of urea were added into 60 mL deionized water under intense stirring. Then the solution was stirred for 10 minutes and transferred to a 100 mL Teflon-lined stainless steel autoclave, heated in an oven at 130 °C for 10 h. After natural cooling to room temperature, the underlying precipitation was washed with deionized water and anhydrous ethanol three times respectively and dried in vacuum at 60 °C for 24 h and the precursor powder was obtained.

Followed by a hydrothermal process with (NH<sub>4</sub>)<sub>2</sub>MoO<sub>4</sub> and Na<sub>2</sub>S·9H<sub>2</sub>O, the precursor was transformed into CoMoO<sub>4</sub>/Co<sub>9</sub>S<sub>8</sub> hybrid nanotubes. In a 100 mL Teflon-lined stainless steel autoclave, the solution with 400 mg of precursor and 1.2 g of Na<sub>2</sub>S·9H<sub>2</sub>O and (NH<sub>4</sub>)<sub>2</sub>MoO<sub>4</sub> (60 wt%) were mixed with 60 mL deionized water under intense stirring for 10 minutes and then heated at 180 °C for 8 h. After natural cooling to room temperature, the as-product of CoMoO<sub>4</sub>/Co<sub>9</sub>S<sub>8</sub> nanotubes was washed with deionized water and anhydrous ethanol and dried in a vacuum oven at 60 °C for

24 h. For comparison, the pure  $\text{Co}_9\text{S}_8$  was synthesized by the same method without the addition of  $(\text{NH}_4)_2\text{MoO}_4$ . And the effect of different contents (20, 40, 60, 80 wt%) of  $(\text{NH}_4)_2\text{MoO}_4$  on the performance of CEs was studied and the relevant  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$  nanotubes were marked  $\text{CoMoO}_4/\text{Co}_9\text{S}_8\text{-x}$  (x = the contents of  $(\text{NH}_4)_2\text{MoO}_4$ , x wt%)

### 2.3. Preparation of $\text{CoMoO}_4/\text{Co}_9\text{S}_8$ counter electrodes

The  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$  CE was prepared by a spin-casting method. Typically, 100 mg as-product of  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$  was added into 10 mL IPA and sonicated for 20 mins. Then the solution was coated on FTO glass by spin-casting for three times at a rate of 4000 rpms for 20 seconds. After every time spin-casting, the FTO substrate was thermally treated at 80 °C for 10 mins and then the next layer was coated. The  $\text{Co}_9\text{S}_8$  CE was fabricated with the same method.

### 2.4. Fabrication of DSSCs

$\text{TiO}_2$  photoanodes consisted of a ~160 nm  $\text{TiO}_2$  under layer, a 12  $\mu\text{m}$   $\text{TiO}_2$  nanocrystalline layer and a scattering layer treating with  $\text{TiCl}_4$  solution. After sensitized with a 0.3 mM N719 dye ethanol solution for 24 h, the  $\text{TiO}_2$  photoanodes absorbed N719 dye were fabricated. In addition, the active areas of photoanodes were about  $0.3 \times 0.4 \text{ cm}^2$ . A DSSC was a sandwich structure assembled with a attaching dye sensitized  $\text{TiO}_2$  photoanode, a CE and a  $\text{I}_3^-/\text{I}^-$  electrolyte between them and employed in having photocurrent-photovoltage (J-V) tests. In a DSSC, cyanoacrylate adhesive was used to adhere these two electrodes together and a vacuum pump was used to inject electrolytes into the cell internal space. The  $\text{I}_3^-/\text{I}^-$  electrolyte was prepared by adding tetraethyl ammonium iodide (0.1 M), tetrabutyl ammonium iodide (0.1 M), tetramethyl ammonium iodide (0.1 M), NaI (0.1 M), KI (0.1 M), LiI (0.1 M),  $\text{I}_2$  (0.05 M), and tBP (0.5 M) into an ACN solution. And a Pt CE ( $2.5 \times 2 \text{ cm}^2$ , prepared by

magnetron sputtering, Wuhan Lattice Solar Energy Technology Co. Ltd, China) was used to be a comparison. A traditional symmetrical cell (CE/electrolyte/CE) was assembled by two identical CEs and used to have electrochemical impedance spectroscopy (EIS) and Tafel tests.

### 2.5. Characterizations and measurements

The crystal structures of  $\text{Co}_9\text{S}_8$  and  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$  were obtained by an X-ray Diffraction (XRD, Bruker D8,  $\text{Cu K}\alpha$ ,  $\lambda=1.5418 \text{ \AA}$ ) at a scan rate of  $5^\circ \text{ min}^{-1}$ . The composition of  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$  was measured by X-ray photoelectron spectroscopy (XPS, ESCALAB 250XI, Thermo). XPS was performed by using  $\text{Al K}\alpha$  ( $h\nu = 1486.6 \text{ eV}$ ) with power of 150 W and beam spot of  $500 \mu\text{m}$ . The XPS data were calibrated by  $\text{C1s}$  ( $284.8 \text{ eV}$ ) and fitted by the XPSPEAK 4.0 software. The surface Morphologies of as-prepared products were performed by field emission scanning electron microscopy (FESEM, SU8010, HITACHI) and the energy-dispersive X-ray (EDX) spectroscopy was used to investigate the element distribution and element types of  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$ -60.

The electrochemical properties of CEs were studied by cyclic voltammetry (CV), EIS and Tafel tests with an electrochemical working station (IM6, Zahner, Germany). CV tests were used to study the electrocatalytic ability of CEs for  $\text{I}_3^-/\text{I}^-$  by a three-electrode cell, in which a as-prepared CE was a work electrode, a Pt sheet was used as CE and an  $\text{Ag}/\text{AgCl}$  was a reference electrode. Meanwhile the tests were performed in an ACN solution of 10 mM  $\text{LiI}$ , 1 mM  $\text{I}_2$ , and 100 mM  $\text{LiClO}_4$  from -0.4 V to 1.4 V with a scan rate of  $50 \text{ mV s}^{-1}$ . EIS measurement was conducted in dark condition and the frequency range was from 100 kHz to 100 mHz under bias voltage of 0 V and the corresponding amplitude of 5 mV. And the ZsimpWin software was used to fit the EIS data. Tafel curves were carried out with a voltage range from 1 V to

1 V and at a scan rate of  $10 \text{ mV s}^{-1}$ .

J-V tests of DSSCs were performed under simulated solar illumination of  $100 \text{ mW cm}^{-2}$  (AM 1.5 G) with a solar simulator (PVIV-94043A, Newport, USA) and a 450W xenon lamp as light source. All the tests were performed five times and the average data were taken.

### 3. Results and discussion

#### 3.1. Morphology and compositions of CEs

155 Figure 1 here

Fig. 1 shows the XRD patterns of the as-prepared  $\text{Co}_9\text{S}_8$ ,  $\text{CoMoO}_4$  and  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$ -60. The as-prepared  $\text{CoMoO}_4$  in the absence of  $\text{Na}_2\text{S}$  has obvious diffraction peaks, which were assigned to the planes of  $\text{CoMoO}_4$  (JCPDS 021-0868). Meanwhile, the  $\text{Co}_9\text{S}_8$  and  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$ -60 both have the same diffraction peaks as the planes of  $\text{Co}_9\text{S}_8$  (JCPDS 65-1765). While there are some other small peaks could be detected in the XRD pattern of  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$ -60 and they can be well indexed to  $\text{CoMoO}_4$ . This indicated that the resulting product was a hybrid material of  $\text{CoMoO}_4$  and  $\text{Co}_9\text{S}_8$ , which was prepared with 60 wt%  $(\text{NH}_4)_2\text{MoO}_4$  in the second hydrothermal process.

165 Figure 2 here

To further research the chemical compositions and the element valence of  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$ -60 CE, XPS was employed in the study and the data were recorded in Fig. 2. Fig. 2a shows the survey scan of  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$  CE, which illustrated the presence of Co, O, Mo and S. Fig. 2b is the high resolution scan of the Mo 3d peak and there is one characteristic doublet of hexavalent molybdenum of Mo 3d at 235.9 and 232.8 eV, which correspond to Mo  $3d_{3/2}$  and Mo  $3d_{5/2}$  orbitals, respectively [36]. Fig. 2c shows the high resolution scan of Co  $2p_{3/2}$  region and there are two obvious

peaks at 780.4 eV and 778.4 eV belong to  $\text{Co}^{2+}$  and  $\text{Co}_9\text{S}_8$  [34, 37]. Fig. 2d shows the core level spectra of S 2p and there are two characteristic doublet of  $\text{Co}_9\text{S}_8$  at 161.4 and 162.5 eV which correspond to S 2p<sub>3/2</sub> and S 2p<sub>1/2</sub>, respectively [37].

Figure 3 here

Fig. 3 is the FESEM and EDX images of the surface morphology of as prepared materials. Fig. 3a shows surface morphology of precursor  $(\text{Co}(\text{CO})_{0.35}\text{Cl}_{0.20}(\text{OH})_{1.10}\cdot 1.74\text{H}_2\text{O})$ , which consists of many nanorods (~200 nm in diameters, and lengths of several micrometers in lengths). After a hydrothermal process of precursor and  $\text{Na}_2\text{S}\cdot 9\text{H}_2\text{O}$ , the as-prepared product of  $\text{Co}_9\text{S}_8$  was transformed into nanotubes with smooth surface (Fig. 3b). While the adding of  $(\text{NH}_4)_2\text{MoO}_4$  in the second hydrothermal process could change the surface morphology of  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$ .  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$ -40 hybrid consisted of some nanotubes and some sheets (Fig. 3c). With the increasing of  $(\text{NH}_4)_2\text{MoO}_4$  content to 60 wt%, the length of  $\text{Co}_9\text{S}_8$  nanotubes was increased and the surface was rougher with  $\text{CoMoO}_4$  nanosheets (Fig. 3d), and this rough surface topography was beneficial to improve the contact of CE and electrolyte and the catalytic activity for the reduction of  $\text{I}_3^-$  to  $\text{I}^-$ . When the  $(\text{NH}_4)_2\text{MoO}_4$  content was 80 wt%, the length of nanotubes of  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$ -80 turned into short and there are many lumps (Fig. 3e). Furthermore,  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$ -90 hybrid was fabricated with layered materials which get together and some nanotubes was attached on the surface of them (Fig. 3f). Fig. 3g is the element mapping of  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$ -60, which Co and S were uniformly distributed in the nanotubes and Mo was distributed in the sheets of the nanotubes surface. Fig. 3h is the EDX spectroscopy confirmed that the composite of  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$ -60 consisted of four elements (Co, Mo, O, S).

The formation mechanism of the  $\text{Co}_9\text{S}_8$  nanotubes can be illustrated by

Kirkendall effect [37, 38]. In the first hydrothermal process, urea could hydrolyze to yield  $\text{OH}^-$  and  $\text{CO}_3^{2-}$  in the solution, and the  $\text{OH}^-$ ,  $\text{CO}_3^{2-}$  and  $\text{Cl}^-$  had a reaction with  $\text{Co}^{2+}$  to form  $\text{Co}(\text{CO})_{0.35}\text{Cl}_{0.20}(\text{OH})_{1.10}$  precipitation (Eqs. (1)-(4)) [39].

In the second step, the as-prepared  $\text{Co}(\text{CO})_{0.35}\text{Cl}_{0.20}(\text{OH})_{1.10}$  reacted with  $\text{Na}_2\text{S}$  and  $(\text{NH}_4)_2\text{MoO}_4$  to fabricate  $\text{Co}_9\text{S}_8$  nanotubes and  $\text{CoMoO}_4$  nanosheets on their surface. Firstly, on the surfaces of nanorods,  $\text{S}^{2-}$  ions and  $\text{Co}(\text{CO})_{0.35}\text{Cl}_{0.20}(\text{OH})_{1.10}$  nanorods react to form a thin layer of  $\text{Co}_9\text{S}_8$  nanocrystallites, which contain many grain boundaries to the benefit of the diffusion and reaction of materials through the  $\text{Co}_9\text{S}_8$  layer. According to Kirkendall effect, the different diffusivities of the different components finally lead to form tubular structures. Meanwhile, the hydrolyzation of  $(\text{NH}_4)_2\text{MoO}_4$  can be expressed as Eqs. (5), and the  $\text{MoO}_4^{2-}$  ions would react with  $\text{Co}(\text{CO})_{0.35}\text{Cl}_{0.20}(\text{OH})_{1.10}$  to fabricate  $\text{CoMoO}_4$  on the surface of  $\text{Co}_9\text{S}_8$  nanotubes.

### 3.2. Electrochemical properties of CEs

Figure 4 here

In order to evaluate the electrochemical property of  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$  CEs and have a comparison with Pt CE, the CV, EIS and Tafel measurements were employed. Fig. S1 shows the effect of  $(\text{NH}_4)_2\text{MoO}_4$  content for the CV of CEs and the absolute values of over potentials ( $\Delta E$ ) and cathodic current density ( $J_{\text{Red-1}}$ ) in left pair of peaks

were recorded in table S1. The values of  $\Delta E$  and  $J_{\text{Red-1}}$  are two important factors to investigate the electrocatalytic activity of CEs for  $\text{I}_3^-/\text{I}^-$ . Smaller  $\Delta E$  and higher values of  $J_{\text{Red-1}}$  indicate the CEs had an excellent electrocatalytic activity. The similar shapes of CV curves indicated these CEs have similar electrocatalytic activity. With the increasing of  $(\text{NH}_4)_2\text{MoO}_4$  content, the electrocatalytic activity was improved. When the  $(\text{NH}_4)_2\text{MoO}_4$  content increased to 60 wt%, the value of  $\Delta E$  was the small and the value of  $J_{\text{Red-1}}$  was the highest. However, further increase the  $(\text{NH}_4)_2\text{MoO}_4$  content, the value of  $\Delta E$  was increased and  $J_{\text{Red-1}}$  was decreased. The reason maybe that the number of  $\text{CoMoO}_4$  sheets was increased and had an aggregation with more contents  $(\text{NH}_4)_2\text{MoO}_4$  in the second hydrothermal process. This greatly prevents the the contact of CE and electrolyte and limits the electronic transmission from CEs to electrolyte, hence the electrocatalytic activity of CEs was decreased. Fig. 4 shows the cyclic voltammograms of  $\text{CoMoO}_4$ ,  $\text{Co}_9\text{S}_8$ ,  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$ -60 and Pt CEs. Though the shapes of CV curves are similar, the  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$  CE has a larger  $J_{\text{Red-1}}$  and smaller  $\Delta E$  than that of pure  $\text{Co}_9\text{S}_8$  CE. Compared to Pt CE, the  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$ -60 CE has a smaller value of  $E_{\text{pp}}$  (0.402 V) and a numerical equivalent  $J_{\text{Red-1}}$  (0.931  $\text{mA cm}^{-2}$ ) (table 1). The result showed fully that the introduction of  $\text{CoMoO}_4$  to  $\text{Co}_9\text{S}_8$  CE could increase the electrocatalytic activity of CE, which was comparable with Pt CE.

Figure 5 here

240

Table 1 here

Fig. 5 shows the Nyquist plots of the symmetric cells with  $\text{Co}_9\text{S}_8$ ,  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$ -60 and Pt CEs. The inset is the equivalent circuit and the relevant

values are summarized in table 1. There are two semicircles and the high-frequency intercept of the left semicircle on the real axis represents the series resistance ( $R_s$ ).

245 And the left semicircle is related to the charge-transfer resistance ( $R_{ct}$ ) at the CE/electrolyte interface, which reflects the catalytic activity of different CEs on the reduction of  $I_3^-$  to  $I^-$ . Fig. S2 shows the EIS of the symmetric cells with CEs prepared by different  $(NH_4)_2MoO_4$  content and the values of  $R_s$  and  $R_{ct}$  were recorded in table S1. Among these CEs, the  $CoMoO_4/Co_9S_8$  CE with 60 wt%  $(NH_4)_2MoO_4$  exhibited

250 smallest values of  $R_s$  and  $R_{ct}$  which indicated that this CE has excellent conductivity and electrocatalytic properties. In Fig. 5, the  $R_s$  of the symmetric cells with  $CoMoO_4/Co_9S_8$ -60 CE is smaller than that of cells with  $Co_9S_8$  CE, which is caused by the introduction of  $CoMoO_4$  to  $Co_9S_8$  and then increased the stronger adhesion of  $CoMoO_4/Co_9S_8$ -60 on FTO. Meanwhile, the value of  $R_{ct}$  for the symmetric cells with

255  $CoMoO_4/Co_9S_8$ -60 CE is  $2.29 \Omega cm^2$ , which is smaller than that of cells with  $Co_9S_8$  CE ( $9.52 \Omega cm^2$ ) and Pt CE ( $5.21 \Omega cm^2$ ). It can be observed that this result is agreed with the data of CV. The small  $R_s$  and  $R_{ct}$  made the DSSCs with  $CoMoO_4/Co_9S_8$ -60 CE have high  $J_{sc}$  and FF.

Figure 6 here

260 Tafel polarization was used to further elucidate the catalytic activity of CEs in Fig. 6 and Fig. S3. Tafel curves described the relationship between overpotential and current density and given the information about the exchange current density ( $J_0$ ), which is the slope in the anodic or cathodic branch. A larger value of  $J_0$  means that the CE has a better electrocatalytic activity for the reduction of  $I_3^-/I^-$ . Fig. S3 shows the

265 Tafel curves of the symmetric cells with CEs prepared by different  $(\text{NH}_4)_2\text{MoO}_4$   
content. Among these CEs, the  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$ -60 CE exhibited a largest value of  $J_0$ ,  
which indicated that this CE has excellent electrocatalytic property. From Fig. 6, the  
value of  $J_0$  for  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$ -60 CE is larger than that of  $\text{Co}_9\text{S}_8$  CE and is similar  
with that of Pt CE. This means that  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$ -60 CE has a highest  
270 electrocatalytic activity for the reduction of  $\text{I}_3^-/\text{I}^-$  among these three CEs. In addition,  
the  $J_0$  has a closely positive correlation with  $R_{\text{ct}}$  as Eqs. (1), which  $R$  is the gas  
constant,  $T$  is absolute temperature,  $n$  is the electron number involved in the reaction  
and  $F$  is Faraday constant. Hence the result of Tafel is consistent with the EIS result  
well.

$$275 \quad J_0 = (RT)/(nFR_{\text{ct}}) \quad (1)$$

### 3.3. Photovoltaic performance of DSSCs

Figure 7 here

Table 2 here

Fig. 7 shows the J-V characteristics of DSSCs assembled by  $\text{Co}_9\text{S}_8$ ,  
280  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$  prepared with 60 wt%  $(\text{NH}_4)_2\text{MoO}_4$  or Pt CEs and the values of  
open-circuit voltage ( $V_{\text{oc}}$ ), short-circuit current density ( $J_{\text{sc}}$ ), fill factor (FF) and PCE  
were summarized in table 2. Compared to  $\text{Co}_9\text{S}_8$  and Pt CEs,  $\text{CoMoO}_4/\text{Co}_9\text{S}_8$  CE  
made the relevant parameters of DSSCs were the largest:  $V_{\text{oc}} = 0.743 \text{ V}$ ,  $J_{\text{sc}} = 17.276$   
 $\text{mA cm}^{-2}$ ,  $\text{FF} = 0.670$  and  $\text{PCE} = 8.60\%$ . Fig. S4 was the J-V curves of CEs with  
285 different  $(\text{NH}_4)_2\text{MoO}_4$  contents and the relevant parameters were recorded in table S2.  
The values of  $V_{\text{oc}}$  for these CEs were similar, and the tendency of  $J_{\text{sc}}$ , FF and PCE

agree with the tendency of CV, EIS and Tafel.

#### 4. Conclusions

In conclusion, this paper prepared CoMoO<sub>4</sub>/Co<sub>9</sub>S<sub>8</sub> hybrid nanotubes by a simple  
290 two-step hydrothermal method. Then this material was coated on FTO glass to  
fabricate a CE by spin-casting. The addition of (NH<sub>4</sub>)<sub>2</sub>MoO<sub>4</sub> in the second  
hydrothermal process, not only made the surface of Co<sub>9</sub>S<sub>8</sub> nanotubes rougher to have  
a good contact between CoMoO<sub>4</sub>/Co<sub>9</sub>S<sub>8</sub> CE and electrolyte, and improved the  
electrochemical property of CoMoO<sub>4</sub>/Co<sub>9</sub>S<sub>8</sub> CE. CV results indicated that the  
295 electrocatalytic activity of CoMoO<sub>4</sub>/Co<sub>9</sub>S<sub>8</sub> CE was similar with Pt CE when the  
(NH<sub>4</sub>)<sub>2</sub>MoO<sub>4</sub> content was 60 wt%. Meanwhile the EIS and Tafel measurements  
demonstrated that the CoMoO<sub>4</sub>/Co<sub>9</sub>S<sub>8</sub> CE had smaller values of R<sub>s</sub> and R<sub>ct</sub> than that of  
Pt CE. The DSSCs assembled with CoMoO<sub>4</sub>/Co<sub>9</sub>S<sub>8</sub> CE exhibited excellent  
photovoltaic property of J<sub>sc</sub> = 17.276 mA cm<sup>-2</sup> and PCE = 8.60%, which were higher  
300 than that of DSSCs with Pt CE (J<sub>sc</sub> = 16.504 mA cm<sup>-2</sup>, PCE = 8.13%). This work used  
a simple approach to prepare a low-cost and high electrochemical property hybrid  
material to fabricate a non-Pt CE in DSSCs.
