This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. This Accepted Manuscript will be replaced by the edited, formatted and paginated article as soon as this is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
Eggshell/Fe$_3$O$_4$ nanocomposite: A novel magnetic nanoparticles coated on porous ceramic eggshell waste as an efficient catalyst in the synthesis of 1,8-dioxo-octahydroxanthene

Elaheh Mosaddegh,* Fatemeh Alsadat Hosseininasab, and Asadollah Hassankhani

Eggshell/Fe$_3$O$_4$ nanocomposite was simply synthesized via an economic and novel method using an aqueous solution of FeSO$_4$ as a starting material and recycled eggshell biowaste as coating agent without any additional alkali and protection atmosphere. Furthermore, the catalytic activity of the magnetic nanocomposite was investigated in the synthesis of 1,8-dioxo-octahydroxanthenes under solvent-free conditions. The reaction proceeds to completion in short reaction time with excellent yield. The suggested strategy for synthesizing 1,8-dioxo-octahydroxanthenes is of great interest because a novel, green, and low-cost magnetic nanocomposite is used as a heterogeneous catalyst, on account of its convenient preparation and high reusability.

Introduction

Natural products with a xanthene heterocyclic motif such as 9-aryl-1,8-dioxo-octahydroxanthenes show a broad spectrum of important biological and pharmaceutical in the field of medicinal chemistry which include antibacterial, antiviral, anti-inflammatory agents, anticancer activities [1-3] and novel CCR1 receptor antagonists [4] as well as their efficiency in the field of material science as dyes [5], laser technologies for visualization of biomolecules, fluorescent markers [6] and luminescent sensors [7]. In this regards, there are several reports on their synthesis in the presence of different catalyst [8-19]. However, the reported methods suffer from drawbacks such as long reaction times, moderate yields, the use of toxic and expensive catalysts and reagents with high catalyst loading, and no agreement with the aspect of green chemistry. Thus, the value of a green and the high effective protocol for this important class of heterocycles depends mainly on identifying a simple, cheap, highly effective and green catalyst [13].

Iron oxide nanoparticles such as magnetite (Fe$_3$O$_4$) have attracted considerable attention in recent years due to their potential applications in magnetic media, catalysis, color imaging, ferrofluids, and biomedicine [20-22]. The most popular methods for preparation of magnetic nano particles (MNPs) are thermal decomposition [23-25] and coprecipitation [26-28]. In the coprecipitation method, Fe$_3$O$_4$ nanoparticles are prepared from a mixture of Fe$^{2+}$ and Fe$^{3+}$ salt solutions by adding an alkali under protective atmosphere [26-28]. Since nanoparticles synthesized by coprecipitation method have attend to be polydisperse in size, the addition of an inorganic coating agent with high thermal stability [29] can be enhanced stability of MNPs [30, 31].

Eggshell (ES) wastes are abundant and inexpensive biomaterials which are composed of more than 90% calcium carbonate [32,33]. ES shows high thermal stability, relatively lower density and phase continuity in the composite compared to mineral CaCO$_3$ [34]. In addition, the porous structure of ES makes it to use less material to form higher surface area compared to artificial one [35]. In this regards, the porous structure of the ES with wide nucleation sites to minimize the aggregation of particles is an excellent host for supporting MNPs. So, in this work, a new and highly effective strategy is used for the synthesis of novel ES/Fe$_3$O$_4$ nanocomposite by using ES bioceramic for coating MNPs via co-precipitation method. To our knowledge, this is the first report to green synthesis of MNPs supported on ES waste as a natural and biocompatible composite. In addition, the catalytic activity of the nanocomposite was investigated in the synthesis of 1,8-dioxo-octahydroxanthenes via one pot multi-component condensation of aryl aldehydes and dimedone in solvent-free and thermal conditions (Scheme 1).

Results and Discussions

Characterization of ES/Fe$_3$O$_4$ nanocomposite

In order to investigate the highest MNPs deposition on the ES surface, different concentrations of Fe$^{3+}$ ion solution were treated...

Fe(OH)$_2$ + FeOOH $\rightarrow$ Fe$_3$O$_4$

It can be seen from the XRD patterns that the main peak at $2\theta$ = 29.4 is related to the major phase of CaCO$_3$ in eggshell structure [41] and the peaks at (220), (311), (400), (422), (511), (440) and (731) are relevant to the phase of Fe$_3$O$_4$ [42]. All diffraction peaks arising from the structure of the nanocomposite are similar to those reported in the literature [40,41]. Further, the presence of iron was approved with energy dispersion x-ray (EDX) analysis of nanocomposite that showed high levels of Fe (38.1%), Ca (27.0%), O (24.9%) and carbon (9.4%) with small amounts of P (0.2%), Zn (0.2) and Na (0.2%). The XRD investigation revealed that the as-synthesized magnetic Fe$_3$O$_4$ and ES NPs have average diameters of 13 and 18 nm respectively as calculated with the Scherrer equation ($D = K\lambda/(\beta \cos \theta)$).

**FTIR spectra analysis**

Comparing the FTIR spectra of ES/Fe$_3$O$_4$ MNPs and eggshell (Fig. 3) shows the typical carbonate absorptions at about 2517 (HCO$_3$), 1799 (CO), 1424, 710 (C–O) and 876 cm$^{-1}$ (OCO) which are according to the literature [42]. The broad band at about 3427 cm$^{-1}$ is due to OH stretching vibration in Ca(OH)$_2$ formed during adsorption of water on the surface of the composite structure. Furthermore, the strong FTIR band observed at around 599 cm$^{-1}$ can be attributed to the Fe-O-Fe stretching vibration mode of Fe$_3$O$_4$ [43].

**Thermo Gravimetric Analysis (TGA)**

The thermal stability of the catalyst was investigated by the thermal gravimetric analysis (TGA) and compared with raw ES (Fig. 4). The differential scanning calorimetry (DSC) and TGA analysis which performed from room temperature to 900 °C indicated that the main weight loss in both raw ES (Fig. 4b) and the ES/Fe$_3$O$_4$ composite (Fig. 4a) is related to the decomposition of ES to CO$_2$ and CaO that proves the existence of the carbonate in the eggshell structure [40]. The measured weight loss below 600°C is due to...
release of physically adsorbed water [36]. So, the catalyst remained stable in the reaction temperature (80 °C).

Electron microscopic investigation
Transmission microscopy (TEM) and field emission scanning electron microscopy (FESEM) of eggshell supported magnetic nanoparticles and raw eggshell have provided in Fig. 5a and b respectively. It is verifying from the comparison of TEM of raw eggshell with the supported one that the Fe₃O₄ MNPs were coated on the surface of the ES as nanoribbon structure. The TEM investigation also showed the average diameter of 13 nm for the magnetic Fe₃O₄ nanoribbon which is in good agreement with the data arising from Scherrer equation. Furthermore, FESEM image showed well dispersion capability of the ES/Fe₃O₄ nanocomposite, which should be due to decreasing of electrostatic force and high surface energy of the magnetic particles after coating with ES. In general, the great dispersion of Fe₃O₄ nanoribbons on the porous structure of eggshell with spherical morphology provides a large contact area for catalyzing the reaction.

VSM analysis
VSM plot of ES/Fe₃O₄ magnetic nanocomposite was shown in Figure 6. The symmetric hysteresis displays, magnetic behaviors of the composite. This is because that the diameter of as-synthesized magnetic nanocomposite (18 nm) is smaller than that of critical threshold of Fe₃O₄ (25 nm) [43]. As shown in Fig. 6a and b, the saturation magnetization of magnetic nanocomposite is smaller.

Fig. 4 TGA curve of (a) ES/Fe₃O₄ MNPs and (b) raw ES.

Fig. 5 TEM and FESEM images of (a) ES/Fe₃O₄ nanocomposite and (b) raw ES.

Fig. 6 VSM plot of a) magnetic nanocomposite and b) pure Fe₃O₄.
than that of pure Fe$_3$O$_4$. This small saturation magnetization (7.68 emu g$^{-1}$) may attribute to the small particle size effect of magnetic nanocomposite since a noncollinear spin arrangement occurs primarily at or near the surface [43]. This phenomena result in the reduction of the magnetic moment in magnetic nanoparticles [44].

### Synthesis of 1,8-dioxo-1,2,3,4,5,6,7,8-octahydroxanthenes

The activity of the nanocatalyst was tested using a one-pot three-component condensation of dimeredone (2 eq) with different aromatic aldehydes (1 eq) under solvent-free and thermal conditions to obtain the corresponding 1,8-dioxo-octahydroxanthenes. Our attempts to synthesis of compound 4 in the absence of the catalyst produced only compound 3 and no cyclization product was obtained even after 5 h (Scheme 1). Next, the optimum amount of nanocatalyst was evaluated in the range of 0.02-0.2 g as summarized in Fig 7. The optimum amount of catalyst was 0.1 g. Further increasing the amount of catalyst did not show significant improvement on the yield or reaction time.

In order to investigate the role of Fe$_3$O$_4$ MNPs in enhancing the catalytic activity of the ES, we decided to carry out comparative reactions in the presence of the ES/Fe$_3$O$_4$, raw ES, pure Fe$_3$O$_4$ and physically mixed ES and Fe$_3$O$_4$ (Table 1). As described in table 2 (entries 1-3), the raw ES is the best catalyst after ES/Fe$_3$O$_4$ nanocomposite and the physically mixed ES-Fe$_3$O$_4$ could not be improved its catalytic activity (entry 3), whereas, the chemical mixture of ES and Fe$_3$O$_4$ could improve the catalytic activity of the ES effectively.

Since almost 90% of the eggshell is composed calcium carbonate and it is the main active site of eggshell catalyst, we carried out a comparative reaction in the presence of CaCO$_3$/Fe$_3$O$_4$ (0.1 g) in the same conditions. Compared with the nanocomposite, the reaction time was too longer and the product yield was low. This proves that eggshell has high porosity with much higher surface area naturally. In summary, the ES/Fe$_3$O$_4$ nanocomposite showed a higher yield in very short reaction time in comparison with the other catalyst. Therefore, the role of the ES/Fe$_3$O$_4$ system as a multifunctional bi-derived catalyst with improved catalytic activity was proven. Furthermore, the generality of this reaction was examined using different aldehydes (Table 2). In all cases, the reactions gave the corresponding products in excellent yields (90-98%) and in very short reaction times (15 min). This method offers significant improvements with regard to the scope of the transformation, simplicity, and green aspects by avoiding expensive, hazardous or corrosive catalysts.

A possible mechanism for the formation of the products is shown in Scheme 2. In this reaction, intermediate 3 was formed through Knoevenagel reaction between dimeredone and aldehyde, and...
subsequently, elimination of water was occurred from the intermediate 3 to give compound 4.

Eco-friendly conditions, ease of separation, stability and reusability of the heterogeneous catalysts are of the most important benefits and make them useful for green commercial and industrial applications. The reusability of the nanocatalyst was examined in the synthesis of 1,8-dioxo-octahydroxanthenes (Table 2, entry 2). The catalyst was recovered magnetically after each run, washed three times with hot EtOH, dried in an oven at 120 °C, and tested for recycling experiment of nanocatalyst.

![Fig.8 Recycling experiment of nanocatalyst.](image)

its activity in subsequent runs (Fig. 8). It was found that the catalyst could be reused five times without any loss of activity. Thus, the new procedure is green, cost effective, clean and more efficient than reported methods with ease of separation of the catalyst from the reaction mixture. This claim is justified through representative examples from more recently published literature with conventional catalyst, illustrated in Table 3.

### Experimental Section

**Materials and Instrument**

All chemicals used in this work, were of analytical reagent grade, purchased from Merck. IR spectra were obtained with MATSON1000 FT-IR spectrophotometer. X-ray diffraction (XRD) with an X-Pert Philips PW340/60 diffractometer (40kV and 30mA) and Cu Kα radiation (λ=0.154 nm) was used to analyze the structure of the composite. TGA experiments were

The Fe aqueous solution with eggshell powder as coating agent via a thermal co-precipitation method. The eggshell powder was prepared according to our previous method [36]. Following, 1.0 g of the ES powder mixed simplicity with 50.0 mL of FeSO₄ solution in the concentration of 25-1000 mg L⁻¹. The suspension was stirred vigorously in a baker at 60 °C. The black ES/Fe₃O₄ nano-composite was produced after 2 h. The resulted particles were magnetically separated and washed with deionized water three times to remove any excess salts from the suspension. The products were then dried at 60 °C for further characterizations.

General procedure for the preparation of 1,8-dioxo-octahydroxanthenes

In a typical general procedure, a mixture of 4-chlorobenzaldehyde (0.14 g, 1 mmol) and dimedone (0.28 g, 2 mmol) in solvent-free condition at 80 °C, were stirred thoroughly in the presence of a catalytic amount of catalyst (0.1 g) to afford the corresponding 1,8-dioxo-octahydroxanthenes in excellent yields. After completion of the reaction (TLC), hot EtOH was added to the reaction mixture and stirred for 5 min. The solid catalyst was magnetically separated from the soluble products and washed with hot EtOH. After cooling, the crude products were precipitated. Pure 1,8-dioxo-octahydroxanthenes were obtained in high yields without any use of more purification. All compounds were known in the literature [8-19] and the NMR and IR spectra of the products were in agreement with earlier data [8-19]. The selected spectral data for four representative, 1,8-dioxo-1,2,3,4,5,6,7,8-octahydroxanthenes are given in supplementary information.

Conclusions

In summary, an efficient, green, and alkali-free synthesis of magnetic ES/Fe₃O₄ nanocomposite has been established without any protective atmosphere by simply heterogeneous stirring FeSO₄ aqueous solution with eggshell powder as coating agent via a thermal co-precipitation method. The Fe₃O₄ NPs showed magnetic properties even after coating. Moreover, a green, rapid and highly efficient protocol for the one-pot synthesis of 1,8-dioxo-octahydroxanthenes has been described under thermal and solvent-free conditions using ES/Fe₃O₄ nanocomposite as a heterogeneous and green catalyst with high catalytic activity and reusability. Finally, the synthesis of nanocomposite based on porous ceramic ES waste is interesting because of the potential to lower cost design new materials in various fields especially in organic transformation and reducing environmental problems.
